

SEA05L

Advanced constant voltage and constant current controller with very efficient LED pilot-lamp driver

Preliminary data

Features

- Constant voltage and constant current control
- Very efficient LED pilot-lamp driver
- Wide operating V_{CC} range (3.5 V - 36 V)
- Low quiescent consumption: 250 μ A
- Voltage reference: 2.5 V
- Voltage control loop accuracy $\pm 0.5\%$
- Current sense threshold: 50 mV
- Current control loop accuracy $\pm 4\%$
- Low external component count
- Open-drain output stage
- SOT23-6L package

Applications

- AC-DC adapter with LED pilot-lamp
- Battery chargers with LED pilot-lamp
- SMPS with LED pilot-lamp

Description

The device is a highly integrated solution for SMPS applications, with an LED pilot-lamp requiring a dual control loop to perform CV (constant voltage) and CC (constant current) regulation.

The IC allows very efficient LED pilot-lamp driving which helps to reduce the standby consumption of the SMPS. It integrates a voltage reference, two op-amps (with OR-ed open-drain outputs), a low-side current sensing circuit and an LED pilot-lamp driver pin implemented with an open-drain mosfet driven by square waveform with 12.5% duty cycle at 1 kHz that allows reducing LED consumption.

Figure 1. Block diagram

The voltage reference, along with one op-amp, is the core of the voltage control loop. The current sensing circuit and the other op-amp make up the current control loop.

The external components needed to complete the two control loops are:

- a resistor divider that senses the output of the power supply and fixes the voltage regulation setpoint at the specified value
- a sense resistor that feeds the current sensing circuit with a voltage proportional to the DC output current; this resistor determines the current regulation setpoint and must be adequately rated in terms of power dissipation
- the frequency compensation components (R-C networks) for both loops.

The device is ideal for space-critical applications.

1 Operation

Table 2. Absolute maximum ratings

Symbol	Pin	Parameter	Value	Unit
V_{CC}	6	DC supply voltage	−0.3 to 38	V
V_{out}	5	Open-drain voltage	−0.3 to V_{CC}	V
I_{out}	5	Max. sink current	20	mA
V_{LD}	4	Open-drain voltage	−0.3 to V_{CC}	V
I_{LD}	4	Max. sink current	15	mA
I_{sense}	1	Analog input	−0.3 to V_{CC}	V
V_{ctrl}	3	Analog input	−0.3 to $V_{CC} < 12^{(1)}$	V

1. V_{ctrl} cannot exceed V_{CC} and cannot exceed 12 V.

Table 3. Thermal data

Symbol	Parameter	Value	Unit
$R_{th\ j-amb}$	Thermal resistance, junction-to-ambient	250	°C/W
T_{Jop}	Junction temperature operating range	−40 to 150	°C
T_{stg}	Storage temperature	−55 to 150	

Figure 2. Pin configuration

Table 4. Pin functions

Pin number	Name	Function
1	I_{sense}	Inverting input of the current loop op-amp. The pin is typically used for the current control loop, connecting it to the positive end of the current sense resistor through a decoupling resistor.
2	GND	Ground. Return of the bias current of the device. 0 V reference for all voltages. The pin has to be tied as close as possible to the ground output terminal of the converter to minimize load current effect on the voltage regulation setpoint.

Table 4. Pin functions (continued)

Pin number	Name	Function
3	Vctrl	Inverting input of the voltage loop op-amp. The pin is typically used for the voltage control loop and is connected to the midpoint of a resistor divider that senses the output voltage.
4	LD	Open-drain output able to sink 5 mA (peak), driven by the internal oscillator at 1 kHz square waveform with 12.5% duty cycle. The internal mosfet starts to switch when V_{CC} is above the turn-on threshold (typ. 3 V) and it is off (LD high impedance) when V_{CC} is below the UVLO of the IC. The pin can be connected to an external LED pilot-lamp with a resistor in series in order to limit the LED current
5	OUT	Common open-drain output of the two internal op-amps. The pin, only able to sink current, is typically connected to the branch of the optocoupler's photodiode to transmit the error signal to the primary side.
6	V_{CC}	Supply voltage of the device. A small bypass capacitor (0.1 μ F typ.) to GND, located as close to the IC pins as possible, might be useful to get a clean supply voltage.

Table 5. Electrical characteristics ($-25\text{ }^{\circ}\text{C} < T_j < 125\text{ }^{\circ}\text{C}$, $V_{CC} = 20\text{ V}$; unless otherwise specified)

Symbol	Parameter	Test condition	Min.	Typ.	Max.	Unit
Device supply						
V_{CC}	Voltage operating range		3.5		36	V
I_{CC}	Quiescent current ($I_{ctrl} = V_{sense} = 0$, $OUT = open$)			250	500	μA
Voltage control loop op-amp						
G_{m_v}	Transconductance (sink current only) ⁽¹⁾		1	3.5		S
V_{ctrl}	Voltage reference default value ⁽²⁾	$T_j = 25\text{ }^{\circ}\text{C}$	2.488	2.5	2.512	V
I_{bias}	Inverting input bias current			25		nA
Current control loop						
G_{m_i}	Transconductance (sink current only) ⁽³⁾		1.5	7		S
V_{csth}	Current sense threshold at $I(lout) = 1\text{ mA}$ ⁽⁴⁾		48	50	52	mV
I_{bias}	Non-inverting input source current			6		μA
Output stage						
V_{OUTlow}	Low output level at 2 mA sink current			200	400	mV
LED driver						
I_{LD}	LED driver sink current capability (peak)		10			mA
f_{LD}	LED driver current modulation frequency		0.6	1	1.4	kHz
V_{LDlow}	Low output level at 5 mA sink current (internal mosfet on)			450	900	mV
I_{LD_LKG}	LED driver leakage current (internal mosfet off)				0.5	μA

1. If the voltage on V_{ctrl} (the negative input of the amplifier) is higher than the positive amplifier input, and it is increased by 1mV, the sinking current at the output OUT will be increased by 3.5 mA.
2. The internal voltage reference is set at 2.5 V. The voltage control loop precision takes into account the cumulative effects of the internal voltage reference deviation as well as the input offset voltage of the transconductance operational amplifier. The internal voltage reference is fixed by bandgap, and trimmed to 0.48 % accuracy at room temperature.
3. When the inverting input at I_{sense} is greater than 50 mV, and the voltage is increased by 1 mV, the sinking current at the output Out will be increased by 7 mA.
4. The internal current sense threshold is triggered when the voltage on pin I_{sense} is 50 mV. The current control loop precision takes into account the cumulative effects of the internal voltage reference deviation as well as the input offset voltage of the transconductance operational amplifier.

Figure 3. Typical application schematic

Voltage control

The voltage loop is controlled via a transconductance operational amplifier, the voltage divider R_1 , R_2 , and the optocoupler which is directly connected to the output. It is possible to choose the values of R_1 and R_2 resistors using [Equation 1](#) and [Equation 2](#):

Equation 1

$$V_o = V_{ctrl} * \frac{(R_1 + R_2)}{R_2}$$

Equation 2

$$R_1 = R_2 * \frac{(V_o + V_{ctrl})}{V_{ctrl}}$$

where V_O is the desired output voltage.

As an example, with $R_1 = 100 \text{ k}\Omega$ and $R_2 = 15 \text{ k}\Omega$ $V_O = 19.17 \text{ V}$.

Current control

The current loop is controlled via a transconductance operational amplifier, the sense resistor R_{sense} , and the optocoupler.

The control equation verifies:

Equation 3

$$R_{\text{sense}} * I_{O\text{max}} = V_{\text{csth}}$$

Equation 4

$$R_{\text{sense}} = \frac{V_{\text{csth}}}{I_{O\text{max}}}$$

where $I_{O\text{max}}$ is the desired limited current, and V_{csth} is the threshold voltage for the current control loop. As an example, with $I_{O\text{max}} = 1 \text{ A}$, $V_{\text{csth}} = 50 \text{ mV}$, then $R_{\text{sense}} = 50 \text{ m}\Omega$.

Note that the R_{sense} resistor should be chosen, taking into account the maximum dissipation (P_{lim}) through it during full load operation.

Equation 5

$$P_{\text{lim}} = V_{\text{csth}} * I_{O\text{max}}$$

As an example, with $I_{O\text{max}} = 1 \text{ A}$ and $V_{\text{csth}} = 50 \text{ mV}$, $P_{\text{lim}} = 50 \text{ mW}$.

Therefore, for most adaptor and battery charger applications, a low-power resistor is suitable for the current sensing function.

V_{csth} threshold is achieved internally by a voltage divider tied to an internal precise voltage reference. Its midpoint is tied to the positive input of the current control operational amplifier, and its endpoint is connected to GND. The resistors of this voltage divider are matched to provide the best precision possible. The current sinking outputs of the two transconductance operational amplifiers are common (to the output of the IC). This makes an OR function which ensures that whenever the current or the voltage reaches excessively high values, the optocoupler is activated.

The relationship between the controlled current and the controlled output voltage can be described with a square characteristic as shown in the following V/I output-power graph (with power supply of the device independent from the output voltage).

Figure 4. Output voltage versus output current

2.2 Compensation

The voltage control transconductance operational amplifier can be fully compensated. Both its output and negative input are directly accessible for external compensation components.

2.3 LD pin function

The device provides a unique feature that allows highly efficient driving of an LED pilot-lamp. The main benefit of this new feature is to allow reducing the standby power consumption of the SMPS with the LED pilot-lamp.

The LD pin is an open-drain output able to sink 5 mA (peak), driven by the internal oscillator at 1 kHz (typ.) square waveform with 12.5% duty cycle (see [Figure 6](#)). The internal mosfet starts to switch when V_{CC} is above the turn-on threshold (typ 3 V) and it is off (LD high impedance) when V_{CC} is below the UVLO of the IC.

Connecting the LED pilot-lamp, with a resistor in series in order to limit the LED current, to pin LD (as shown in [Figure 5](#)) reduces the power consumption of the LED while keeping the same driving peak current. The LED driving current modulation frequency of 1 kHz (typ.) eliminates the visual perception of flickering.
