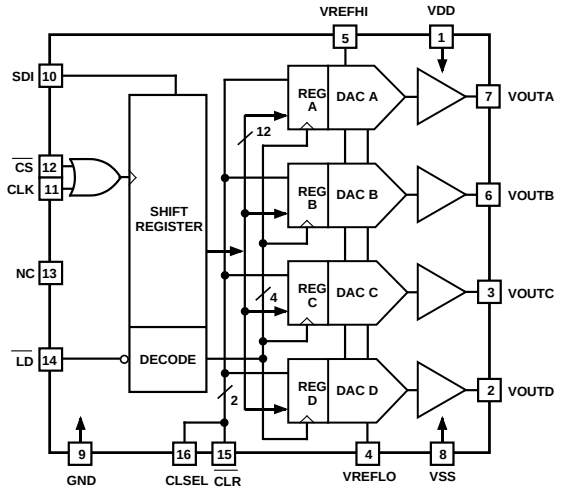
Quad 12-Bit Serial Voltage Output DAC

DAC8420

FEATURES
Guaranteed Monotonic Over Temperature
Excellent Matching Between DACs
Unipolar or Bipolar Operation
Buffered Voltage Outputs
High Speed Serial Digital Interface
Reset to Zero- or Center-Scale
Wide Supply Range, +5 V-Only to ±15 V
Low Power Consumption (35 mW max)
Available in 16-Pin DIP and SOL Packages

APPLICATIONS
Software Controlled Calibration
Servo Controls
Process Control and Automation
ATE

FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

The DAC8420 is a quad, 12-bit voltage-output DAC with serial digital interface, in a 16-pin package. Utilizing BiCMOS technology, this monolithic device features unusually high circuit density and low power consumption. The simple, easy-to-use serial digital input and fully buffered analog voltage outputs require no external components to achieve specified performance.

The three-wire serial digital input is easily interfaced to microprocessors running at 10 MHz rates, with minimal additional circuitry. Each DAC is addressed individually by a 16-bit serial word consisting of a 12-bit data word and an address header. The user-programmable reset control $\overline{\text{CLR}}$ forces all four DAC outputs to either zero or midscale, asynchronously overriding the current DAC register values. The output voltage range, determined by the inputs VREFHI and VREFLO, is set by the user for positive or negative unipolar or bipolar signal swings within the supplies allowing considerable design flexibility.

The DAC8420 is available in 16-pin epoxy DIP, cerdip, and wide-body SOL (small-outline surface mount) packages. Operation is specified with supplies ranging from +5 V-only to ±15 V, with references of +2.5 V to ±10 V respectively. Power dissipation when operating from ±15 V supplies is less than 255 mW (max), and only 35 mW (max) with a +5 V supply.

For applications requiring product meeting MIL-STD-883, contact your local sales office for the DAC8420/883 data sheet, which specifies operation over the –55°C to +125°C temperature range.

Lead Temperature (Soldering, 60 sec) ..... +300°C

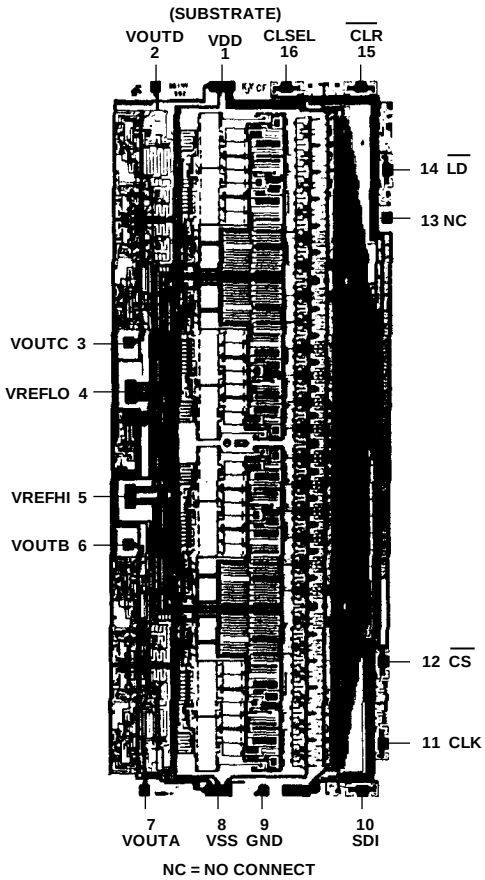
Package Type	Thermal Resistance θ_{JA}	θ_{JC}	Units
16-Pin Plastic DIP (P)	70[1]	27	°C/W
16-Pin Hermetic DIP (Q)	82[1]	9	°C/W
16-Lead Small Outline Surface Mount (S)	86[2]	22	°C/W

NOTES
[1]θ_{JA} is specified for worst case mounting conditions, i.e., θ_{JA} is specified for device in socket.
[2]θ_{JA} is specified for device on board.

CAUTION

1. Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation at or above this specification is not implied. Exposure to the above maximum rating conditions for extended periods may affect device reliability.
2. Digital inputs and outputs are protected, however, permanent damage may occur on unprotected units from high-energy electrostatic fields. Keep units in conductive foam or packaging at all times until ready to use. Use proper antistatic handling procedures.
3. Remove power before inserting or removing units from their sockets.
4. Analog Outputs are protected from short circuits to ground or either supply.

DICE CHARACTERISTICS



Die Size 0.119 × 0.283 inch, 33,677 sq. mils (3.023 × 7.188 mm, 21.73 sq. mm)
Transistor Count 2,207

For additional DICE ordering information, refer to databook.

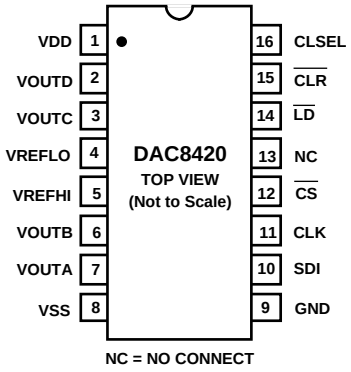
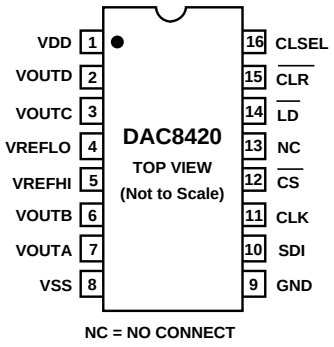
PIN CONFIGURATIONS

DIP



SOL



PIN FUNCTION DESCRIPTION

Power Supplies

VDD: Positive Supply, +5 V to +15 V.
VSS: Negative Supply, 0 V to –15 V.
GND: Digital Ground.

Clock

CLK: System Serial Data Clock Input, TTL/CMOS levels. Data presented to the input SDI is shifted into the internal serial-parallel input register on the rising edge of clock. This input is logically ORed with $\overline{CS}$.

Control Inputs

(All are CMOS/TTL compatible.)

$\overline{CLR}$: Asynchronous Clear, active low. Sets internal data registers A-D to zero or midscale, depending on current state of CLSEL. The data in the serial input shift register is unaffected by this control.

CLSEL: Determines action of $\overline{CLR}$. If HIGH, a Clear command will set the internal DAC registers A-D to midscale (800_H). If LOW, the registers are set to zero (000_H).

$\overline{CS}$: Device Chip Select, active low. This input is logically ORed with the clock and disables the serial data register input when HIGH. When LOW, data input clocking is enabled, see the Control Function Table.

$\overline{LD}$: Asynchronous DAC Register Load Control, active low. The data currently contained in the serial input shift register is shifted out to the DAC data registers on the falling edge of $\overline{LD}$, independent of $\overline{CS}$. Input data must remain stable while $\overline{LD}$ is LOW.

Data Input

(All are CMOS/TTL compatible.)

SDI: Serial Data Input. Data presented to this pin is loaded into the internal serial-parallel shift register, which shifts data in beginning with DAC address Bit A1. This input is ignored when $\overline{CS}$ is HIGH.

The format of the 16-bit serial word is:

(FIRST)															(LAST)
B0	B1	B2	B3	B4	B5	B6	B7	B8	B9	B10	B11	B12	B13	B14	B15
A1	A0	NC	NC	D11	D10	D9	D8	D7	D6	D5	D4	D3	D2	D1	D0
—Address Word—				(MSB)			—DAC Data Word—								(LSB)

NC = Don't Care.

Reference Inputs

VREFHI: Upper DAC ladder reference voltage input. Allowable range is (V_{DD} – 2.5 V) to (V_{VREFLO} +2.5 V).

VREFLO: Lower DAC ladder reference voltage input, equal to zero scale output. Allowable range is V_{SS} to (V_{VREFHI} – 2.5 V).

Analog Outputs

VOUTA through VOUTD: Four buffered DAC voltage outputs.

Table I. Control Function Logic Table

CLK[1]	$\overline{CS}$[1]	$\overline{LD}$	$\overline{CLR}$	CLSEL	Serial Input Shift Register	DAC Registers A-D
NC	H	H	L	H	No Change	Loads Midscale Value (800_H)
NC	H	H	L	L	No Change	Loads Zero-Scale Value (000_H)
NC	H	H	↑	H/L	No Change	Latches Value
↑	L	H	H	NC	Shifts Register One Bit	No Change
L	↑	H	H	NC	Shifts Register One Bit	No Change
H	NC (↑)	↓	H	NC	No Change	Loads the Serial Data Word[2]
H	NC	L	H	NC	No Change	Transparent[3]
NC	H	H	H	NC	No Change	No Change

NC = Don't Care.

NOTES
[1]$\overline{CS}$ and CLK are interchangeable.
[2]Returning $\overline{CS}$ HIGH while CLK is HIGH avoids an additional "false clock" of serial input data. See Note 1.
[3]Do not clock in serial data while $\overline{LD}$ is LOW.

OPERATION

Introduction

The DAC8420 is a quad, voltage-output 12-bit DAC with serial digital input, capable of operating from a single +5 V supply. The straightforward serial interface can be connected directly to most popular microprocessors and microcontrollers, and can accept data at a 10 MHz clock rate when operating from ±15 V supplies. A unique voltage reference structure assures maximum utilization of DAC output resolution by allowing the user to set the zero- and full-scale output levels within the supply rails. The analog voltage outputs are fully buffered, and are capable of driving a 2 kΩ load. Output glitch impulse during major code transitions is a very low 64 nV-s (typ).

Digital Interface Operation

The serial input of the DAC-8420, consisting of $\overline{CS}$, SDI, and $\overline{LD}$, is easily interfaced to a wide variety of microprocessor serial ports. As shown in Table I and the Timing Diagram, while $\overline{CS}$ is LOW the data presented to the input SDI is shifted into the internal serial/parallel shift register on the rising edge of the clock, with the address MSB first, data LSB last. The data format, shown above, is two bits of DAC address and two "don't care" fill bits, followed by the 12-bit DAC data word. Once all 16 bits of the serial data word have been input, the load control $\overline{LD}$ is strobed and the word is parallel-shifted out onto the internal data bus. The two address bits are decoded and used to route the 12-bit data word to the appropriate DAC data register, see the Applications Information.

Correct Operation of $\overline{CS}$ and CLK

As mentioned in Table I, the control pins CLK and $\overline{CS}$ require some attention during a data load cycle. Since these two inputs are fed to the same logical "OR" gate, their operation is in fact identical. The user must take care to operate them accordingly in order to avoid clocking in false data bits. As shown in the Timing Diagram, CLK must be either halted HIGH, or $\overline{CS}$ brought HIGH during the last HIGH portion of the CLK following the rising edge which latched in the last data bit. Otherwise, an additional rising edge is generated by $\overline{CS}$ rising while CLK is LOW, causing $\overline{CS}$ to act as the clock and allowing a false data bit into the serial input register. The same issue must be considered in the beginning of the data load sequence also.

Using $\overline{CLR}$ and CLSEL

The CLEAR ($\overline{CLR}$) control allows the user to perform an asynchronous reset function. Asserting $\overline{CLR}$ loads all four DAC data word registers, forcing the DAC outputs to either zero-scale (000_H) or midscale (800_H), depending on the state of CLSEL as shown in the Digital Function Table. The CLEAR function is asynchronous and is totally independent of $\overline{CS}$. When $\overline{CLR}$ returns HIGH, the DAC outputs remain latched at the reset value until $\overline{LD}$ is strobed, reloading the individual DAC data word registers with either the data held in the serial input register prior to the reset, or new data loaded through the serial interface.

Table II. DAC Address Word Decode Table

A1	A0	DAC Addressed
0	0	DAC A
0	1	DAC B
1	0	DAC C
1	1	DAC D

Programming the Analog Outputs

The unique differential reference structure of the DAC8420 allows the user to tailor the output voltage range precisely to the needs of the application. Instead of spending DAC resolution on an unused region near the positive or negative rail, the DAC8420 allows the user to determine both the upper and lower limits of the analog output voltage range. Thus, as shown in Table III and Figure 1, the outputs of DACs A through D range between VREFHI and VREFLO, within the limits specified in the Electrical Characteristics tables. Note also that VREFHI must be greater than VREFLO.

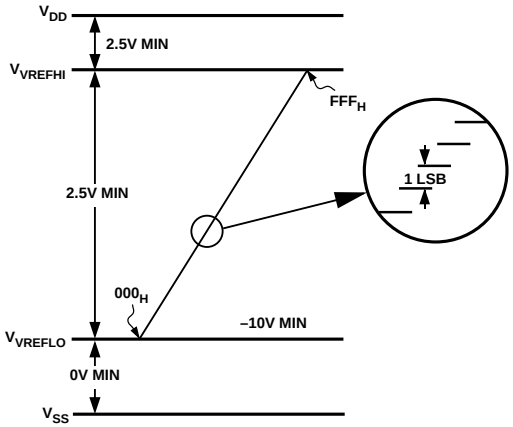


Figure 1. Output Voltage Range Programming

Table III. Analog Output Code

DAC Data Word (HEX)	V_{OUT}	Note
FFF	$VREFLO + \frac{(VREFHI - VREFLO)}{4096} \times 4095$	Full-Scale Output
801	$VREFLO + \frac{(VREFHI - VREFLO)}{4096} \times 2049$	Midscale + 1
800	$VREFLO + \frac{(VREFHI - VREFLO)}{4096} \times 2048$	Midscale
7FF	$VREFLO + \frac{(VREFHI - VREFLO)}{4096} \times 2047$	Midscale – 1
000	$VREFLO + \frac{(VREFHI - VREFLO)}{4096} \times 0$	Zero Scale

VREFHI Input Requirements

The DAC8420 utilizes a unique, patented DAC switch driver circuit which compensates for different supply, reference voltage, and digital code inputs. This ensures that all DAC ladder switches are always biased equally, ensuring excellent linearity under all conditions. Thus, as indicated in the specifications, the VREFHI input of the DAC8420 will require both sourcing and sinking current capability from the reference voltage source. Many positive voltage references are intended as current sources only, and offer little sinking capability. The user should consider references such as the AD584, AD586, AD587, AD588, AD780, and REF43 in this application.

APPLICATIONS

Power Supply Bypassing and Grounding

In any circuit where accuracy is important, careful consideration of the power supply and ground return layout helps to ensure the rated performance. The DAC8420 has a single ground pin that is internally connected to the digital section as the logic reference level. The first thought may be to connect this pin to the digital ground; however, in large systems the digital ground is often noisy because of the switching currents of other digital circuitry. Any noise that is introduced at the ground pin could couple into the analog output. Thus, to avoid error causing digital noise in the sensitive analog circuitry, the ground pin should be connected to the system analog ground. The ground path (circuit board trace) should be as wide as possible to reduce any effects of parasitic inductance and ohmic drops. A ground plane is recommended if possible. The noise immunity of the onboard digital circuitry, typically in the hundreds of millivolts, is well able to reject the common-mode noise typically seen between system analog and digital grounds. Finally, the analog and digital ground should be connected together at a single point in the system to provide a common reference. This is preferably done at the power supply.

Good grounding practice is essential to maintaining analog performance in the surrounding analog support circuitry as well. With two reference inputs, and four analog outputs capable of moderate bandwidth and output current, there is a significant potential for ground loops. Again, a ground plane is recommended as the most effective solution to minimizing errors due to noise and ground offsets.

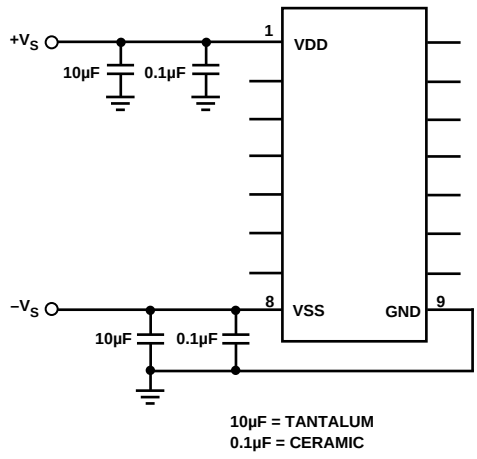

Figure 26. Recommended Supply Bypassing Scheme

The DAC8420 should have ample supply bypassing, located as close to the package as possible. Figure 26 shows the recommended capacitor values of 10 µF in parallel with 0.1 µF. The 0.1 µF cap should have low "Effective Series Resistance" (ESR) and "Effective Series Inductance" (ESI), such as the common ceramic types, which provide a low impedance path to ground at high frequencies to handle transient currents due to internal logic switching. In order to preserve the specified analog performance of the device, the supply should be as noise free as possible. In the case of 5 V only systems it is desirable to use the same 5 V supply for both the analog circuitry and the digital portion of the circuit. Unfortunately, the typical 5 V supply is extremely noisy due to the fast edge rates of the popular CMOS logic families which induce large inductive voltage spikes, and busy microcontroller or microprocessor busses which commonly have large current spikes during bus activity. However, by properly filtering the supply as shown in Figure 27, the digital 5 V supply can be used. The inductors and capacitors generate a filter that not only rejects noise due to the digital circuitry, but also filters out the lower frequency noise of switch mode power supplies. The analog supply should be connected as close as possible to the origin of the digital supply to minimize noise pickup from the digital section.

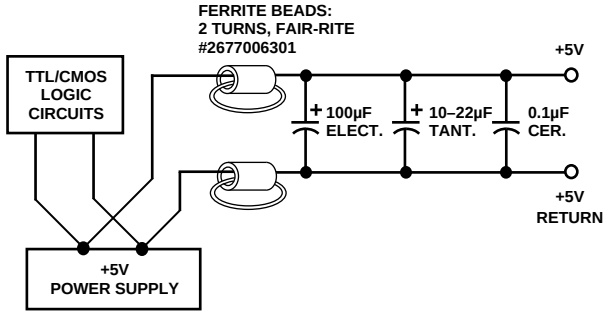

Figure 27. Single-Supply Analog Supply Filter

Analog Outputs

The DAC8420 features buffered analog voltage outputs capable of sourcing and sinking up to 5 mA when operating from ±15 V supplies, eliminating the need for external buffer amplifiers in most applications while maintaining specified accuracy over the rated operating conditions. The buffered outputs are simply an op amp connected as a voltage follower, and thus have output characteristics very similar to the typical operational amplifier. These amplifiers are short-circuit protected. The designer should verify that the output load meets the capabilities of the device, in terms of both output current and load capacitance. The DAC8420 is stable with capacitive loads up to 2 nF typical. However, any capacitive load will increase the settling time, and should be minimized if speed is a concern.

The output stage includes a p-channel MOSFET to pull the output voltage down to the negative supply. This is very important in single supply systems, where VREFLO usually has the same potential as the negative supply. With no load, the zero-scale output voltage in these applications will be less than 500 µV typically, or less than 1 LSB when V_{VREFHI} = 2.5 V. However, when sinking current this voltage does increase because of the finite impedance of the output stage. The effective value of the pull-down resistor in the output stage is typically 320 Ω. With a 100 kΩ resistor connected to +5 V, the resulting zero-scale output voltage is 16 mV. Thus, the best

single supply operation is obtained with the output load connected to ground, so the output stage does not have to sink current.

Like all amplifiers, the DAC8420 output buffers do generate voltage noise, 52 nV/√Hz typically. This is easily reduced by adding a simple RC low-pass filter on each output.

Reference Configuration

The two reference inputs of the DAC8420 allow a great deal of flexibility in circuit design. The user must take care, however, to observe the minimum voltage input levels on VREFHI and VREFLO to maintain the accuracy shown in the data sheet. These input voltages can be set anywhere across a wide range within the supplies, but must be a minimum of 2.5 V apart in any case. See Figure 1. A wide output voltage range can be obtained with ±5 V references, which can be provided by the AD588 as shown in Figure 28. Many applications utilize the DACs to synthesize symmetric bipolar wave forms, which requires an accurate, low drift bipolar reference. The AD588 provides both voltages and needs no external components. Additionally, the part is trimmed in production for 12-bit accuracy over the full temperature range without user calibration. Performing a Clear with the reset select CLSEL HIGH allows the user to easily reset the DAC outputs to midscale, or zero volts in these applications.

When driving the reference inputs VREFHI and VREFLO, it is important to note that VREFHI both sinks and sources current, and that the input currents of both are code dependent. Many voltage reference products have limited current sinking capability and must be buffered with an amplifier to drive VREFHI, in order to maintain overall system accuracy. The input VREFLO, however, has no such requirement.

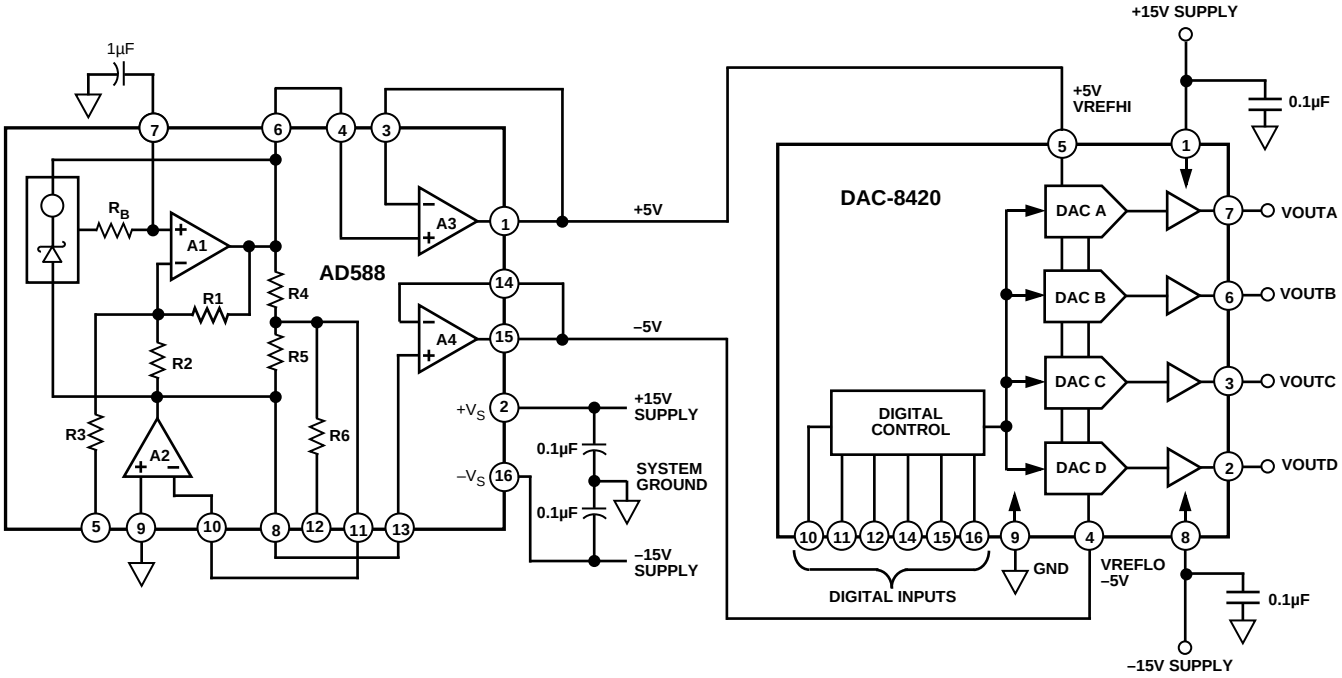

Figure 28. ±10 V Bipolar Reference Configuration Using the AD588

For a single 5 V supply, V_{VREFHI} is limited to at most 2.5 V, and must always be at least 2.5 V less than the positive supply to ensure linearity of the device. For these applications, the REF43 is an excellent low drift 2.5 V reference that consumes only 450 μA (max). It works well with the DAC8420 in a single 5 V system as shown in Figure 29.

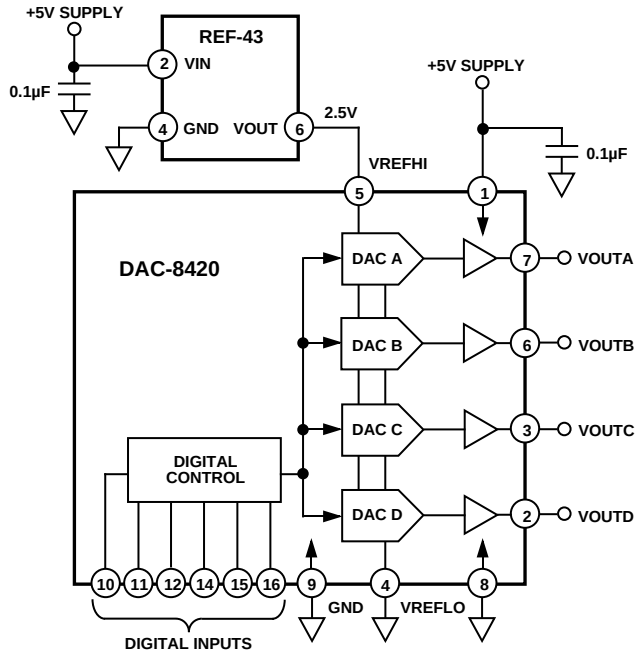

Figure 29. +5 V Single Supply Operation Using REF43

Isolated Digital Interface

Because the DAC8420 is ideal for generating accurate voltages in process control and industrial applications, due to noise, safety requirements, or distance, it may be necessary to isolate it from the central controller. This can be easily achieved by using opto-isolators, which are commonly used to provide electrical isolation in excess of 3 kV. Figure 30 shows a simple 3-wire interface scheme to control the clock, data, and load pulse. For normal operation, $\overline{CS}$ is tied permanently LOW so that the DAC8420 is always selected. The resistor and capacitor on the $\overline{CLR}$ pin provide a power-on reset with 10 ms time constant. The three opto-isolators are used for the SDI, CLK, and $\overline{LD}$ lines.

One opto-isolated line ($\overline{LD}$) can be eliminated from this circuit by adding an inexpensive 4-bit TTL Counter to generate the Load pulse for the DAC8420 after 16 clock cycles. The counter is used to count of the number of clock cycles loading serial data to the DAC8420. After all 16 bits have been clocked into the converter, the counter resets, and a load pulse is generated on clock 17. In either circuit, the DAC8420's serial interface provides a simple, low cost method of isolating the digital control.

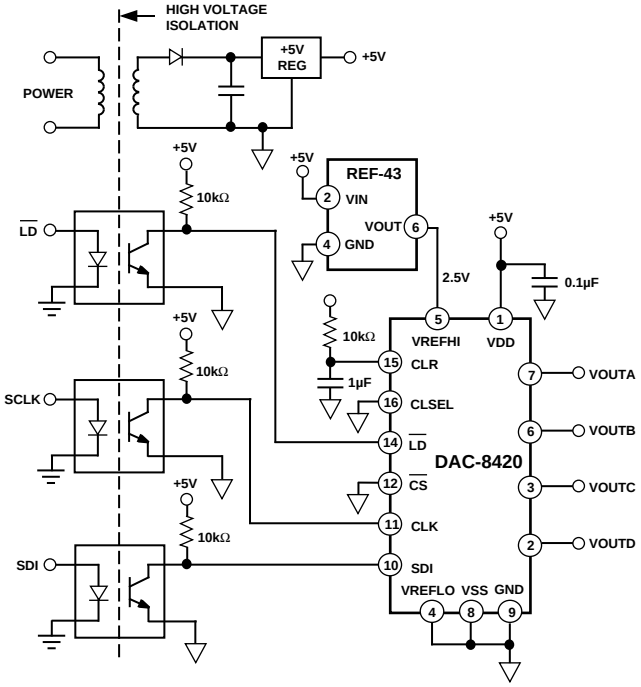

Figure 30. Opto-Isolated 3-Wire Interface

Dual Window Comparator

Often a comparator is needed to signal an out-of-range warning. Combining the DAC8420 with a quad comparator such as the CMP04 provides a simple dual window comparator with adjustable trip points as shown in Figure 31. This circuit can be operated with either a dual or a single supply. For the A input channel, DAC B sets the low trip point and DAC A sets the upper trip point. The CMP04 has open-collector outputs that are connected together in "Wired-OR" configuration to generate an out-of-range signal. For example, when VINA goes below the trip point set by DAC B, comparator C2 pulls the output down, turning the red LED on. The output can also be used as a logic signal for further processing.

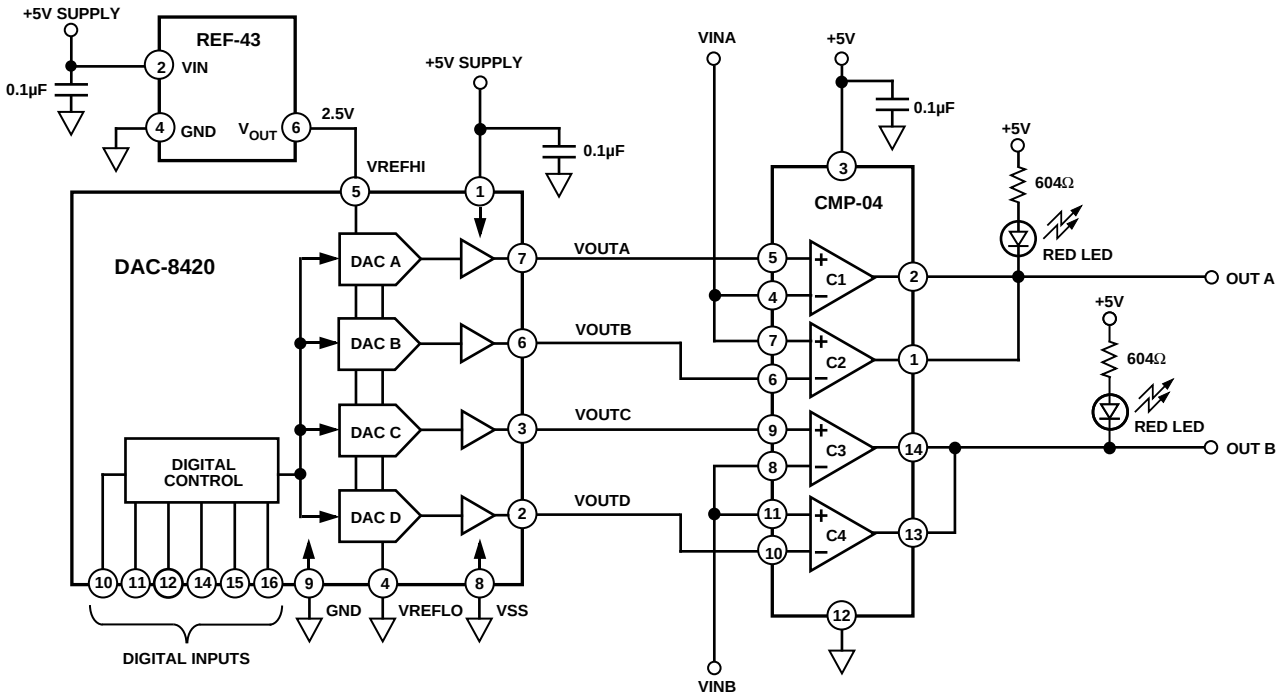

Figure 31. Dual Programmable Window Comparator

MC68HC11 Microcontroller Interfacing

Figure 32 shows a serial interface between the DAC8420 and the MC68HC11 8-bit microcontroller. The SCK output of the 68HC11 drives the CLK input of the DAC, and the MOSI port outputs the serial data to load into the SDI input of the DAC. The port lines PD5, PC0, PC1, and PC2 provide the controls to the DAC as shown.

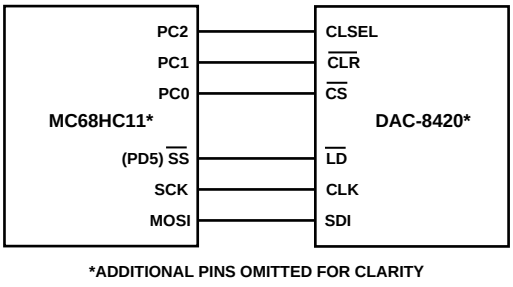

Figure 32. MC68HC11 Microcontroller Interface

For correct operation, the 68HC11 should be configured such that its CPOL bit and CPHA bit are both set to 1. In this configuration, serial data on MOSI of the 68HC11 is valid on the rising edge of the clock, which is the required timing for the DAC8420 Data is transmitted in 8-bit bytes (MSB first), with only eight rising clock edges occurring in the transmit cycle. To load data to the DAC8420's input register, PC0 is taken low and held low during the entire loading cycle. The first 8 bits are shifted in address first, immediately followed by another 8 bits in the second least-significant byte to load the complete 16-bit word. At the end of the second byte load, PC0 is then taken high. To prevent an additional advancing of the internal shift register, SCK must already be asserted before PC0 is taken high. To transfer the contents of the input shift register to the DAC register, PD5 is then taken low, asserting the $\overline{LD}$ input of the DAC and completing the loading process. PD5 should return high before the next load cycle begins. The DAC8420's $\overline{CLR}$ input, controlled by the output PC1, provides an asynchronous clear function.
