

Low voltage dual brush DC motor driver

Datasheet - production data

Description

The STSPIN240 is a dual brush DC motor driver integrating a low $R_{DS(ON)}$ power stage in a small QFN 3 x 3 mm package.

Both the full-bridges implement an independent PWM current controller with fixed OFF time.

The device is designed to operate in battery-powered scenarios and can be forced into a zero-consumption state allowing a significant increase in battery life.

The device offers a complete set of protection features including overcurrent, overtemperature and short-circuit protection.

Features

- Operating voltage from 1.8 to 10 V
- Maximum output current 1.3 A_{rms}
- $R_{DS(ON)}$ HS + LS = 0.4 Ω typ.
- Current control with programmable off-time
- Full protection set
 - Non-dissipative overcurrent protection
 - Short-circuit protection
 - Thermal shutdown
- Energy saving and long battery life with standby consumption less than 80 nA

Applications

Battery-powered DC motor applications such as:

- Toys
- Portable printers
- Robotics
- Point of sale (POS) devices
- Portable medical equipment
- Healthcare and wellness devices (shavers and toothbrushes)

R_{STBY}	18 k Ω
C_{RCOFF}	22 nF
R_{RCOFF}	1 k Ω
R_{OFF}	47 k Ω ($t_{OFF} \approx 37 \mu\text{s}$)

Figure 3. Typical application schematic

6 Functional description

The STSPIN240 is a dual brush DC motor driver integrating two PWM current controllers and a power stage composed by two fully-protected full-bridges.

6.1 Standby and power-up

The device provides a low settable consumption mode forcing the STBY\RESET input below the V_{STBYL} threshold.

When the device is in standby status, the power stage is disabled (outputs are in high impedance) and the supply to the integrated control circuitry is cut off.

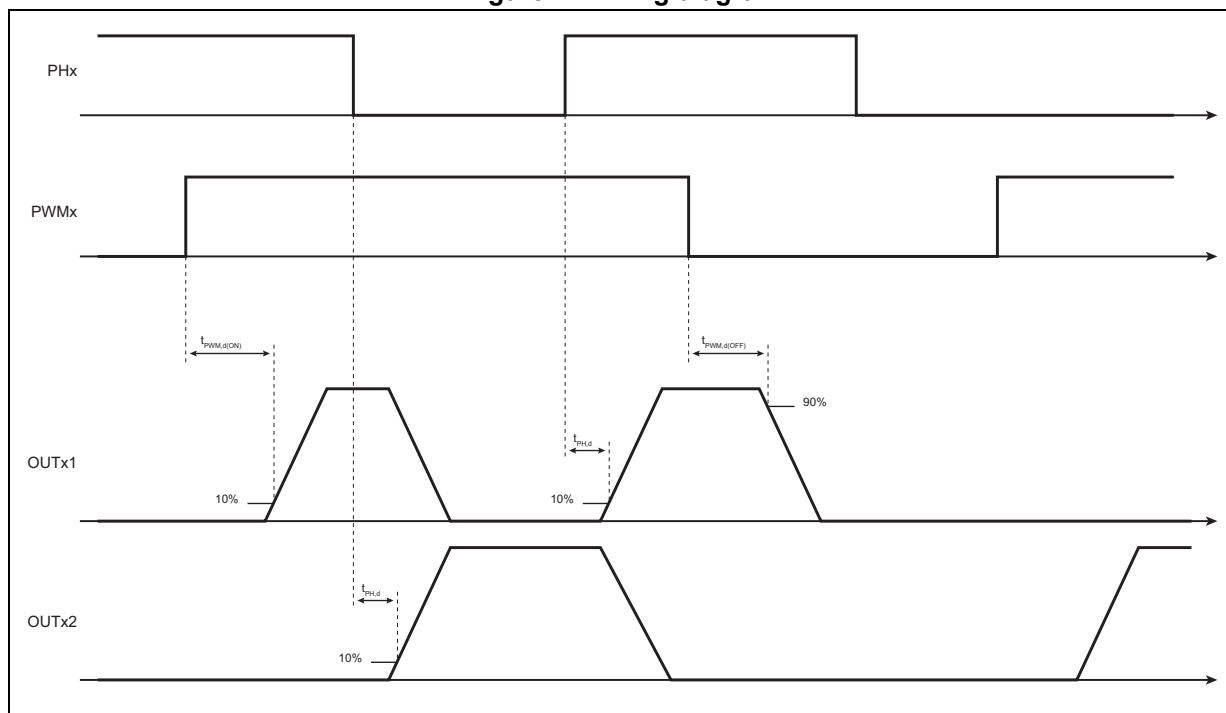

6.2 Motor driving

The outputs of each bridge are controlled by the respective PWMx and PHx inputs as listed in [Table 8](#).

Table 8. Truth table

ENFAULT	PHx	PWMx	OUTx1	OUTx2	Full-bridge condition
0	X	X	HiZ	HiZ	Disabled
1	0	0	GND	GND	Both LS on
1	0	1	GND	VS	HS2 and LS1 on (current X1 ← X2)
1	1	0	GND	GND	Both LS on
1	1	1	VS	GND	HS1 and LS2 on (current X1 → X2)

Figure 4. Timing diagram

6.3 PWM current control

The device implements two independent current controllers, one for each full-bridge.

The voltage on the sense pins (V_{SENSEA} and V_{SENSEB}) is compared to the reference voltage applied on the REF pin (V_{REF}).

When $V_{SENSEX} > V_{REF}$, the current limiter is triggered, the OFF time counter is started and the decay sequence is performed.

The decay sequence starts turning on both low sides of the full-bridge.

Table 9. ON and slow decay states

PHx	PWMx	ON	Decay
0	0	HSx1 = OFF LSx1 = ON HSx2 = OFF LSx2 = ON	N.A. ⁽¹⁾
0	1	HSx1 = OFF LSx1 = ON HSx2 = ON LSx2 = OFF	HSx1 = OFF LSx1 = ON HSx2 = OFF LSx2 = ON
1	0	HSx1 = OFF LSx1 = ON HSx2 = OFF LSx2 = ON	N.A. ⁽¹⁾
1	1	HSx1 = ON LSx1 = OFF HSx2 = OFF LSx2 = ON	HSx1 = OFF LSx1 = ON HSx2 = OFF LSx2 = ON

1. During decays the inputs values are ignored until the system returns to ON condition (decay time expired).

The reference voltage value, V_{REF} , has to be selected according to the load current target value (peak value) and sense resistors value.

Equation 1

$$V_{REF} = R_{SNSx} \cdot I_{LOAD,peak}$$

In choosing the sense resistor value, two main issues must be taken into account:

- The sensing resistor dissipates energy and provides dangerous negative voltages on the SENSE pins during the current recirculation. For this reason the resistance of this component should be kept low (using multiple resistors in parallel will help to obtain the required power rating with standard resistors).
- The lower is the R_{SNSx} value, the higher is the peak current error due to noise on the V_{REF} pin and to the input offset of the current sense comparator: too low values of R_{SNSx} must be avoided.

Figure 5. PWM current control

TOFF adjustment

The decay time is adjusted through an external resistor connected between the TOFF pin and ground as shown in [Figure 6](#). A small RC series must be inserted in parallel with the regulator resistor in order to increase the stability of the regulation circuit according to indications listed in [Table 10](#).

Figure 6. OFF time regulation circuit

The relation between the OFF time and the external resistor value is shown in the graph of [Figure 7](#). The value typically ranges from 10 μs to 150 μs .

Table 10. Recommended R_{RCOFF} and C_{RCOFF} values according to R_{OFF}

R_{OFF}	R_{RCOFF}	C_{RCOFF}
$10\text{ k}\Omega \leq R_{OFF} < 82\text{ k}\Omega$	1 k Ω	22 nF
$82\text{ k}\Omega \leq R_{OFF} \leq 160\text{ k}\Omega$	2.2 k Ω	22 nF

Figure 7. OFF time vs. R_{OFF} value

6.4 Overcurrent and short-circuit protections

The device embeds circuitry protecting each power output against the overload and short-circuit conditions (short to ground, short to VS and short between outputs).

When the overcurrent or the short-circuit protection is triggered, the power stage is disabled and the EN\FAULT input is forced low through the integrated open drain MOSFET discharging the external C_{EN} capacitor.

The power stage is kept disabled and the open drain MOSFET is kept ON until the EN\FAULT input falls below the V_{RELEASE} threshold, then the C_{EN} capacitor is charged through the R_{EN} resistor.

Figure 8. Overcurrent and short-circuit protections management

The total disable time after an overcurrent event can be set by properly sizing the external network connected to the EN\FAULT pin (refer to [Figure 9](#) and [Figure 10](#)):

Equation 2

$$t_{DIS} = t_{discharge} + t_{charge}$$

But t_{charge} is normally much higher than t_{discharge}, thus we can consider only the second one contribution:

Equation 3

$$t_{DIS} \cong R_{EN} \cdot C_{EN} \cdot I_n \frac{(V_{DD} - R_{EN} \cdot I_{PDEN}) - V_{RELEASE}}{(V_{DD} - R_{EN} \cdot I_{PDEN}) - V_{IH}}$$

Where V_{DD} is the pull-up voltage of the R_{EN} resistor.

Figure 9. Disable time versus R_{EN} and C_{EN} values ($V_{DD} = 3.3\text{ V}$)

Figure 10. Disable time versus R_{EN} and C_{EN} values ($V_{DD} = 1.8\text{ V}$)

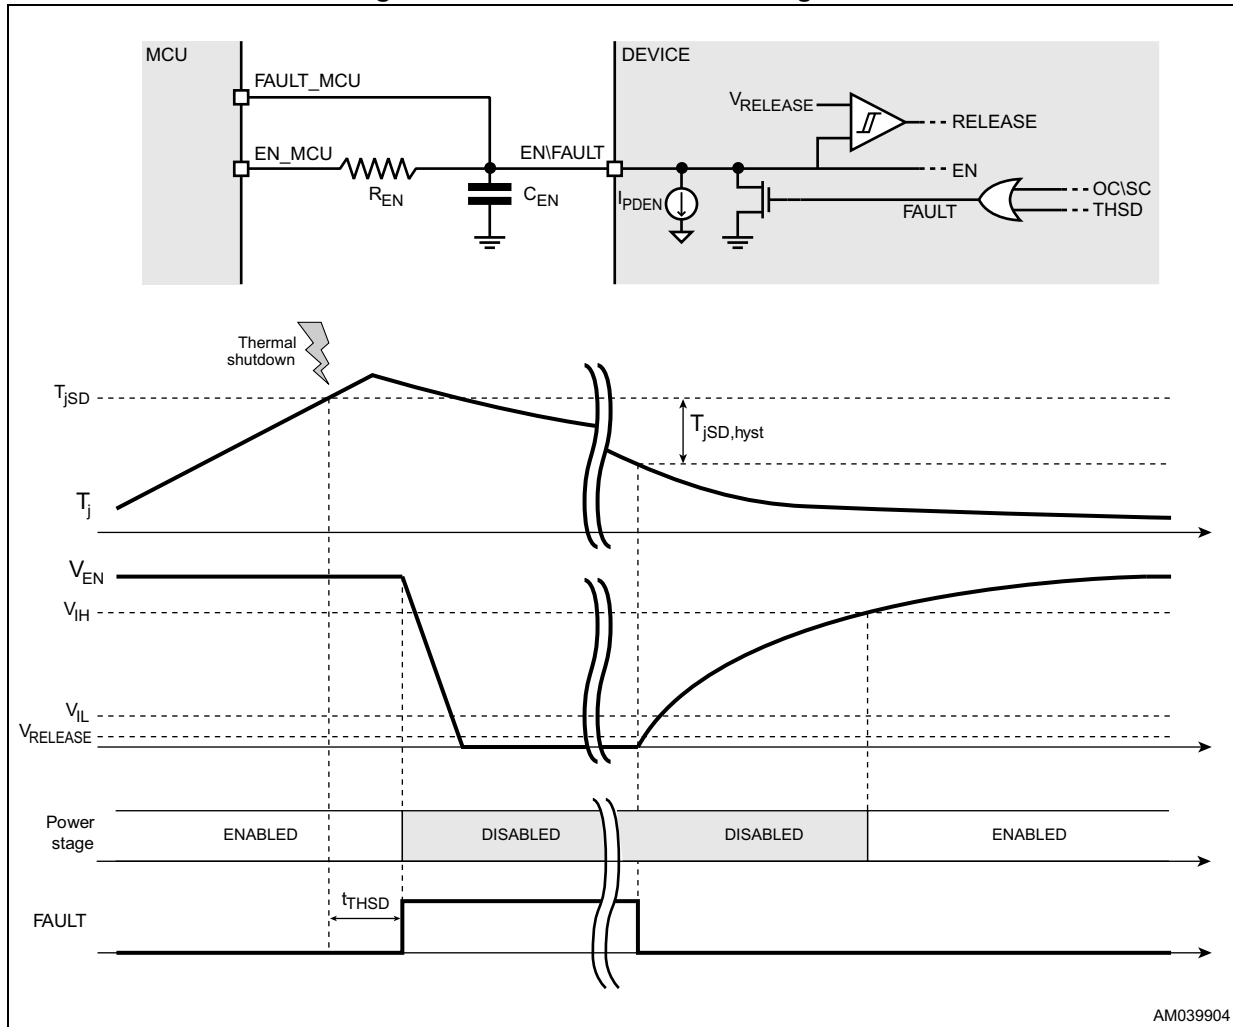

6.5 Thermal shutdown

The device embeds circuitry protecting it from overtemperature conditions.

When the thermal shutdown temperature is reached, the power stage is disabled and the EN\FAULT input is forced low through the integrated open drain MOSFET.

The protection and the EN\FAULT output are released when the IC temperature returns below a safe operating value ($T_{jSD} - T_{jSD,Hyst}$).
