

High Efficiency 6-CH LED Backlight Driver with Dual LCD Bias Power

Features

- Backlight LED Driver
 - Wide input range: 2.7V~5.5V
 - High efficiency step-up LED driver with 6-Ch current sinks, up to 40V boost voltage.
 - Up to 30mA/Ch in backlight mode
 - $\pm 0.7\%$ current matching at 20mA
 - $\pm 2.2\%$ current accuracy at 20mA
 - I²C/PWM dual dimming control scheme
 - High resolution I²C 11-bit linear or exponential dimming
 - Wide range PWM dimming
 - 100Hz to 100kHz frequency
 - 0.2% to 100% duty cycle at 20kHz
- Programmable current sink turn on/off ramp time/shape and transition ramp up/down time
- 1.0MHz typical boost switching frequency
- Programmable input PWM hysteresis to minimize jitter at low PWM duty cycle
- Programmable OVP and current limitation
- LED open/short protection
- LCD Panel Bias
 - Wide input range: 2.7V~5.5V
 - Programmable dual output Bias regulator using a single inductor
 - Programmable ramp time for OUTP and OUTN
 - Charge pump PFM mode at light load
 - LCD Bias efficiency: up to 85%
 - Wide dual output voltage range $\pm 4.0V$ to $\pm 6.3V$ (50mV/step) and output current up to 200mA at $V_{IN} \geq 2.9V$
 - Active output discharge function
 - Current limitation and short protection
- Others
 - System level input UVLO
 - Thermal shutdown protection
 - Low shutdown current $< 1\mu A$
 - Flexible I²C interface
 - Pb-free Packages: WLCSP-28
 - RoHS and Green Compliant
 - -40°C to +85°C Temperature Range

Applications

- Tablet Backlight and Bias

Brief Description

KTZ8866 is the ideal power solution for LED backlighting and LCD bias power of medium size panels. It integrates a step-up converter for LED backlighting, a step-up converter with LDO and inverting charge pump for LCD bias power, resulting in a simpler and smaller solution with fewer external components. High switching frequency allows the use of a smaller inductor and capacitor. Its input operating range is from 2.7V to 5.5V, accommodating 1-cell lithium ion batteries or 5V supply.

The LED driver's six regulated current sinks can regulate up to 30mA with its maximum boost output voltage up to 40V. 11-bit linear or exponential I_{LED} resolution can be obtained over I²C or PWM dimming. For additional flexibility, PWM dimming offers wide range frequency and duty cycle to support Content Adaptive Brightness Control (CABC).

The LCD bias power section includes a step-up converter, LDO and an inverting charge pump to generate dual outputs, OUTP and OUTN, whose voltages can be programmed via an I²C interface. By integrating synchronous rectification MOSFETs for the step-up converter and charge pump, the KTZ8866 maximizes conversion efficiency up to 85%.

Various protection features are built into KTZ8866, including inductor current limit protection, output short circuit protection, output over-voltage protection, LED fault (open or short) protection and thermal shutdown protection.

KTZ8866 is equipped with I²C interface for various controls and status monitor.

KTZ8866 is available in a RoHS and Green compliant 28-ball 1.73mm x 2.92mm x 0.62mm WLCSP package.

Typical Application

Pin Descriptions

Pin #	Name	Function
A1	OUTN	Charge pump output pin of the negative power. Bypass with a 10μF ceramic capacitor to PGND_CHP.
A2	CFLY2	Negative charge pump flying capacitor negative connection.
A3	PGND_CHP	Power ground for negative charge pump.
A4	CFLY1	Negative charge pump flying capacitor pin positive connection.
B1	VIN	Input supply pin for the IC, bypass with a 10μF ceramic capacitor to GND.
B2	ENN	Enable pin for negative power (OUTN), 300KΩ pull down resistor to GND
B3	ENP	Enable pin for positive power (OUTP), 300KΩ pull down resistor to GND
B4	OUTP	LDO output pin of the positive power, bypass with a 10μF ceramic capacitor.
C1	S1	Regulated output current sink #1.
C2	SCL	Clock of the I ² C interface.
C3	SDA	Bi-directional data pin of the I ² C interface.
C4	REG	LCD-Bias Boost converter output pin, bypass a 10μF ceramic capacitor to PGND_LCD
D1	S2	Regulated output current sink #2.
D2	PWM	PWM dimming input pin, 300kΩ pull-down resistor at this pin to GND.
D3	HWEN	Active high hardware enable pin, 400kΩ pull-down resistor to GND.
D4	LX_LCD	Switching node of the LCD Bias boost converter.
E1	S3	Regulated output current sink #3.
E2	SGND	Ground pin for sink driver.
E3	AGND	Analog ground pin.
E4	PGND_LCD	Power ground for LCD Bias power supply boost converter.
F1	S4	Regulated output current sink #4.
F2	VOUT	Output voltage sense pin of the step-up converter.
F3, F4	PGND_BL	Power Ground for LED boost converter.
G1	S5	Regulated output current sink #5.
G2	S6	Regulated output current sink #6.
G3, G4	LX_BL	Switching pin of the LED step-up converter.

Functional Block Diagram

Functional Description

Overview

KTZ8866 is the ideal power solution for LED backlighting and LCD bias power of small and medium size panels. It integrates a step-up converter for LED backlighting, a step-up converter with LDO and inverting charge pump for LCD bias power, resulting in a simpler and smaller solution with fewer external components. High switching frequency allows the use of smaller inductors and capacitors. Its operating input ranges from 2.7V to 5.5V, accommodating 1-cell lithium ion batteries or 5V supply.

The LED driver's six regulated current sinks can regulate up to 30mA in backlight mode with its maximum boost output voltage up to 40V. 11bit linear or exponential I_{LED} resolution can be obtained over I²C or PWM dimming. For additional flexibility, PWM dimming offers wide range frequency and duty cycle to support Content Adaptive Brightness Control (CABC).

The LCD bias power includes a step-up converter, LDO and an inverting charge pump to generate dual outputs, OUTP and OUTN, whose voltages can be programmed via an I²C interface. By integrating synchronous rectification MOSFETs for the step-up converter and charge pump, the KTZ8866 maximizes conversion efficiency up to 85%.

Various protection features are built into KTZ8866, including inductor current limit protection, output short circuit protection, output over-voltage protection, LED fault (open or short) protection and thermal shutdown protection. KTZ8866 is equipped with I²C interface for various controls and status monitor.

Hardware Enable & Standby Mode

KTZ8866 has a logic input HWEN pin to enable/disable the device. When HWEN is set low, the device goes into shutdown mode, all I²C registers are reset to default, and the I²C interface is disabled. Under this condition, the device does not respond to any I²C command. Even when SCL/SDA's pull up voltage is much less than VIN voltage, it will not cause any extra leakage current.

When HWEN is set high, the device goes into standby mode, the I²C interface is enabled, and the device can respond to I²C command. Under this condition, if SCL/SDA's pull up voltage is much less than VIN voltage, it can cause a small leakage current from VIN. For example, if VIN = 4.2V and SCL/SDA's pull up voltage is 1.8V, there will be around 6.8μA additional leakage current from VIN in this standby mode.

Based on HWEN's connection, there are two kinds of power-up sequences as below

- If HWEN is tied to VIN, once VIN goes above around 2.0V, HWEN should stay high for at least $T_{I2C_RESET} = 150\mu s$ time before any I²C command can be accepted.
- If HWEN is driven by a GPIO, once HWEN goes from low to high, HWEN should stay high for at least $T_{I2C_RESET} = 150\mu s$ time before receiving any I²C command.

Either HWEN input or I²C command can be used to turn off the part, but there are some differences.

- If setting HWEN input low to turn off the part, the I_{LED} will be turned off immediately without any ramp down control. After that, the I²C interface is disabled.
- If using an I²C command to turn off backlight while keeping HWEN high, the I_{LED} will have ramp down control. After the LED current ramp down is finished, the I²C interface is still alive waiting for new command.

Backlight Boost

A step-up converter is used to generate high voltage for driving LED strings. An adaptive control method automatically adjusts output voltage by monitoring the headroom voltage of current sinks. In this way, KTZ8866 can offer much better efficiency. The switching frequency of KTZ8866 Backlight Boost is typical 1.0MHz.

Backlight Current Sink Setting

Each current sink can be enabled or disabled by register 0x08 bits [5:0]. They can be enabled by writing the backlight enable bit to HIGH in register 0x08 bit [6] after correctly setting of LED configuration and brightness. If a current sink is not used, connect its output to GND. During the startup, KTZ8866 will automatically detect and disable the corresponding channel.

When PWM dimming is enabled and a non-zero PWM duty cycle is detected, the KTZ8866 multiplies the duty cycle with I²C brightness settings. Figure 2 and Figure 3 describe the start-up timing for operation with I²C controlled current and with PWM controlled current.

Figure 2. Enable of KTZ8866 via I²C

Figure 3. Enable of KTZ8866 via PWM

Operating Mode Description

The KTZ8866 backlight can operate in different modes, see Table 1 below

Table 1. Backlight Operating Modes

HWEN	BL_EN 0x08[6]	PWM INPUT	I ² C BRIGHTNESS 0x05[7:0] 0x04[2:0]	CURRENT SINKs ENABLEs 0x08[5:0]	PWM_EN 0x02[0]	FEEDBACK DISABLEs 0x10[6:1]	MAPPING MODE 0x02[3]	ACTION
0	X	X	X	X	X	X	X	Shutdown

1	1	X	≥0x001	≥000001	0	<111111	0 = Exp. Mode 1 = Lin. Mode	-Backlight boost enabled -Selected current sink(s) enabled -I ² C control only
1	1	Duty = 0	X	≥000001	1	<111111	X	Standby ⁷
1	1	Duty > 0	≥0x001	≥000001	1	<111111	0 = Exp. Mode 1 = Lin. Mode	-Backlight boost enabled -Selected current sink(s) enabled -I ² C × PWM control
1	1	Duty > 0	≥0x001	≥000001	1	111111	0 = Exp. Mode 1 = Lin. Mode	-Backlight boost disabled -Selected current sink(s) enabled -I ² C × PWM control

7. Standby signifies that the backlight boost and current sinks are shut down. Register writes are still possible. Shutdown signifies that the device was reset and no I²C communication is accepted.

Backlight LED Current

The LED current is always a DC current (not PWM). It can be programmed for either exponential mapping mode or linear mapping mode by Register 0x02 bit [3]. These two modes determine the transfer characteristic of dimming code to LED current. It also has 11-bit control, including the 8-bit MSBs from register 0x05 bits [7:0] and the 3-bit LSBs from register 0x04 bits [2:0]. If only 8-bit dimming is needed, the 3-bit LSBs should be kept as '111' while the 8-bit MSBs are programmed. If 11-bit dimming ratio is needed, the 3-bit LSBs should be programmed first, then the 8-bit MSBs are programmed. Only programming the 3-bit LSBs doesn't change the current ratio until the 8-bit MSBs are programmed.

In linear mapping 8-bit dimming mode, the LED current per channel can be calculated as:

$$I_{LED_BL} = I_{LED_FS} * D_{PWM} * \left(\frac{3}{2050} + \frac{Code * 8 + 7}{2050} \right), \quad (Code = 0 \sim 255)$$

where I_{LED_FS} is the backlight full-scale LED current which is programmed by 0x15 bits [7:3], ranges from 5.2mA to 30mA with 0.8mA step, D_{PWM} is the input PWM duty cycle if PWM dimming is enabled, otherwise $D_{PWM} = 1$.

In linear mapping 11-bit dimming mode, the LED current per channel can be calculated as:

$$I_{LED_BL} = I_{LED_FS} * D_{PWM} * \left(\frac{3}{2050} + \frac{Code}{2050} \right), \quad (Code = 1 \sim 2047)$$

For linear mapping 11-bit dimming's Code 0, current sink and boost converter will be disabled, LED will be turned off.

In exponential mapping 8-bit dimming mode, the LED current per channel can be calculated as:

$$I_{LED_BL} = I_{LED_FS} * D_{PWM} * \frac{1.003040572^{(Code * 8 + 7)}}{500} \quad (Code = 0 \sim 255)$$

In exponential mapping 11-bit dimming mode, the LED current per channel can be calculated as:

$$I_{LED_BL} = I_{LED_FS} * D_{PWM} * \frac{1.003040572^{Code}}{500} \quad (Code = 1 \sim 2047)$$

For exponential mapping 11-bit dimming's Code 0, current sink and boost converter will be disabled, LED will be turned off.

Backlight Brightness Control Mode

KTZ8866 has two brightness control mode, I²C Only Mode and I²C x PWM Mode, see Figure 4. In I²C Only Mode, register 0x02's bit [0] PWM_ENABLE should be set to "0", the LED brightness is controlled by registers 0x04 and 0x05. In I²C x PWM Mode, register 0x02's bit [0] PWM_ENABLE should be set to "1", the LED brightness will be controlled by I²C code and PWM duty together.

If the LED current is changed from one value to the other by I²C dimming Register 0x04 and Register 0x05, the ramp time can help LED current transit smoothly from one brightness level to next one. Ramp time can be adjusted from 1μs to 640ms via 0x03's bits [6:3]. Ramp time applies both to ramp up and ramp down, it remains same regardless the amount of change in brightness.

Figure 4. I²C and PWM Dimming Scheme

Backlight PWM Dimming

In backlight I²C x PWM Mode, the input PWM duty cycle is converted internally to produce a DC output sink current (not pulsing). When PWM is enabled, it can be programmed as either active high or active low by register 0x02's bit [2], with active high as default. When PWM dimming is enabled, KTZ8866 uses internal 20MHz sampling clock to detect the PWM duty cycle. It is recommended to have the minimum PWM on time as 0.1μs. For the example of 20kHz dimming frequency, the PWM duty cycle range can be 0.2%~100%. The PWM dimming frequency range can be as wide as 100Hz to 100kHz.

PWM Dimming Step Response and Timeout

If the LED current is changed from one value to the other by PWM dimming duty cycle, the transition ramp up/down time can be programmed by Register 0x15 bits [2:0]. For this transition ramp, its slope is fixed, so the final transition ramp time is dependent on the change amount of the PWM duty cycle.

The KTZ8866 PWM timeout feature turns off the boost output when the PWM is enabled and there is no PWM pulse detected.

PWM to Digital Code Readback

In I²C x PWM control mode, registers 0x12 and 0x13 contain the PWM duty cycle to the 11-bit code conversion information. Register 0x12 contains the 8 LSBs of the brightness code and register 0x13 the 3 MSBs. They are suggested to be read out in successive way to make sure the PWM duty result is correct. Too long delay between reading them may cause incorrect returned result, since input PWM duty may change during the delay time. To translate this reading to the actual LED current setting of the KTZ8866, convert it to the corresponding duty cycle and multiply it by the brightness level setting in the brightness registers (0x04 and 0x05).

Backlight PWM Hysteresis

In backlight mode, if PWM dimming frequency is high and PWM dimming duty cycle is low, even the internal fast 20MHz sampling clock's sampling error can be sufficient to cause the output LED current jitter. KTZ8866 implements PWM hysteresis control to minimize the jitter. It can be programmed by register 0x03 bits [2:0]. The input PWM duty cycle is converted to an internal 11-bit digital value, this PWM hysteresis decides how many LSBs of this 11-bit digital value is changed before the output LED current can follow the change. When PWM duty cycle changes in the same direction, no hysteresis exists. Only when the PWM duty cycle's change starts to go in different direction, does the hysteresis starts to take effect, and only when the change is larger or equal to the number of LSBs programmed, the output LED current starts to follow the change. Table 2 shows the relationship between the minimum LSB(s) and the PWM duty cycle hysteresis. Table 3 summarizes register 0x03 bits [2:0]'s minimum setting to prevent jitter under different input PWM frequency conditions. The drawback of setting PWM hysteresis too high is that the output current becomes less accurate due to the hysteresis.

Table 2. PWM Hysteresis

PWM Register 0x03 Bits [2:0]	Minimum LSB(s)	PWM Duty Cycle Hysteresis
000	0	0/2047 = 0%
001	2	2/2047 = 0.10%
010	4	4/2047 = 0.20%
011	6	6/2047 = 0.29%
100	8	8/2047 = 0.39%
101	10	10/2047 = 0.48%
110	12	12/2047 = 0.59%
111	14	14/2047 = 0.68%

Table 3. Register 0x03 Bits [2:0]'s Minimum Setting

PWM Dimming Frequency (kHz)	Sampling Error	Register 0x03 Bits [2:0]'s Minimum Setting to Prevent Jitter
0.1	0.0005%	001
1	0.005%	001
5	0.025%	001
10	0.05%	001
20	0.1%	010
40	0.2%	011
100	0.5%	110

Turn On/Off Ramp

When backlight mode is enabled from standby mode or disabled to standby mode, the LED current waveform's turn on/off time is controlled by Turn On/Off Ramp Register 0x14 bits [7:4] and bits [3:0] respectively. The 16 options range from 512μs to 16384ms, with 8ms as default. The shape of the turn on/off ramp in backlight mode can also be programmed as exponential or linear through the Register 0x02 bit [1], with linear as default.

LED Fault Protection

Each current sink is protected against LED short or open conditions. The outcome of LED short event depends on the setting of LED_SHORT_MODE bit in register 0x10. If it is '1' and LED short circuit condition arises, the current sink continues to regulate until $V_{SINK} > V_{SOV}$. When any sink node voltage goes above V_{SOV} (6V) for more than 59ms (typ.), LED_SHORT flag will be set in 0x0F and that channel's current sink will be turned off, and the other channel(s) will continue to work if they don't trigger this fault condition. If it is '0', the LED_SHORT flag will be set in 0x0F when $V_{SINK} > V_{SOV}$ more than 59ms(typ.) is detected, but KTZ8866 will keep working as usual without turning off the shorted channel's current sink until it reaches thermal shutdown.

In case of an LED failing open, the current sink voltage of the failed string will go close to ground and dominate the boost converter control loop. As a result, the output voltage will increase until it reaches the over-voltage threshold set by register 0x02. Once an OVP event has been detected, the boost will stop switching and the BL_OVP flag will be set in register 0x0F. The outcome of OVP event depends on the setting of OVP_MODE bit in register 0x02. If OVP_MODE is set to 0, the LED open channel will not be disabled, as soon as V_{BL_OUT} falls below the backlight OVP threshold, the KTZ8866 begins switching again, so that V_{BL_OUT} will be kept close to OVP threshold. Once the opened channel resumes to connected later, its LED current will resume and V_{BL_OUT} will go back to normal level. If OVP_MODE is set to 1, once the over-voltage incident is triggered, the BL_OVP flag is set in register 0x0F. Any of the enabled current sink headroom voltage drops below 150mV will be disabled. Then the output voltage of the boost converter will go back to normal level. During the entire process, the rest of the LED string (healthy LED string) would continue in normal operation. Even if the open channel is reconnected later, its LED current will not resume until toggling HWEN or sending software reset command or resetting backlight mode.

In case where all LED channels are open, once the output voltage of the boost converter reaches the over-voltage threshold, all the current sinks will be disabled internally and the boost converter will stop switching. User needs to restart the IC by toggling HWEN or sending software reset command or resetting backlight mode.

Backlight Over Current Protection

The KTZ8866 has 4 different OCP thresholds (1.2A, 1.6A, 2.0A, and 2.5A) chosen by register 0x11 bits [1:0]. It is a cycle-by-cycle current limit by detecting low side power FET current. Once the threshold is triggered, the low side power FET will be turned off immediately for the rest of the switching cycle time. If enough overcurrent threshold events occur, the BL_OCP Flag (register 0x0F, bit [0]) will be set.

LCD Bias Boost Converter

REG pin is the output of a high efficiency boost which is used to generate OUTP and OUTN power rails. REG boost ranges from 4V to 6.6V with 50mV step size. OUTP is generated by an LDO whose input is REG pin. OUTP ranges from 4V to 6.3V with 50mV step size and supports up to 200mA output current. OUTN is generated by an inverting charge pump whose input is REG pin. OUTN ranges from -6.3V to -4V with 50mV step size and supports up to 200mA output current. Refer to 0x0C, 0x0D, 0x0E for the settings of REG, OUTP and OUTN.

For proper operation, REG voltage is suggested to be $REG = MAX(OUTP, |OUTN|) + V_{HR}$, where $V_{HR} \geq 200mV$ for lower currents and $V_{HR} \geq 300mV$ for higher currents.

OUTP and OUTN voltage settings can be changed while they are enabled, but user must re-write 0x09 to get new settings taking effect. The REG voltage changes immediately upon a register write. The LCD Bias outputs can be turned on/off either by ENP and ENN pins or by 0x09 register bits [2:1]. EXT_EN bit in 0x09 is used to select on/off is controlled by external pins or internal register bits. Refer to Table 4 for detailed information.

Table 4. LCD Bias Power Operating Mode

HWEN	ENN	ENP	LCD_EN_MODE 0x09[7]	OUTP_EN 0x09[2]	OUTN_EN 0x09[1]	EXT_EN 0x09[0]	ACTION
0	X	X	X	X	X	X	Device shutdown
1	0	0	0	X	X	1	Standby ⁸
1	X	X	1	0	0	0	Standby ⁸
1	0	1	1	X	X	1	V _{OUTP} enabled via external input
1	1	0	1	X	X	1	V _{OUTN} enabled via external input
1	1	1	1	X	X	1	V _{OUTP} and V _{OUTN} enabled via external Input
1	X	X	1	1	0	0	V _{OUTP} enabled via I ² C
1	X	X	1	0	1	0	V _{OUTN} enabled via I ² C
1	X	X	1	1	1	0	V _{OUTP} and V _{OUTN} enabled via I ² C

8. Standby signifies that OUTP and OUTN are either high impedance or being internally pulled low via the active pulldown, and that the LCD boost is off. Shutdown signifies that the device was reset and no I²C communication is accepted.

Fast Discharge

KTZ8866 has internal switch resistance for discharging OUTP and OUTN when device is shutdown. The OUTP discharge function is enabled with register 0x09 bit [4] and the OUTN discharge is enabled with register 0x09 bit [3].

OUTP Short Circuit Protection

If output current of OUTP is greater than 240mA (typical), the OUTP_SHORT flag will be set in register 0x0F. A I²C readback is required to clear the flag. The outcome of an OUTP_SHORT detection depends on the setting of register 0x0A bits [7:6], including report-only flag, shutdown OUTP/OUTN, and shutdown OUTP/OUTN and backlight. KTZ8866 provides four level short circuit detection filter: 100μs, 500μs, 1ms, and 2ms by register 0x0B bits [3:2] to avoid false trigger problems.

OUTN Short Circuit Protection

OUTN_SHORT flag will be set in register 0x0F if OUTN is found shorted to ground. An I²C readback of register 0x0F is required to clear the flag. The outcome of an OUTN_SHORT detection depends on the setting of register 0x0A bits [7:6], including report-only flag, shutdown OUTP/OUTN, and shutdown OUTP/OUTN and backlight. KTZ8866 provides four level short circuit detection filter options: 100μs, 500μs, 1ms, and 2ms by register 0x0B bits [1:0] to avoid false trigger problems.

Soft Reset

All the I²C registers can be reset to their default settings by writing '1' to the SOFTWARE_RESET bit in Register 0x08, this bit will be reset to '0' automatically after the software reset.

UVLO

Under voltage lock-out (UVLO) featured is included to monitor the input voltage VIN. Once VIN drops below UVLO falling threshold, the current sinks are disabled and the boost converters stop switching. After VIN increases above UVLO rising threshold, the boost converters and the current sinks will resume to their previous setting.

Thermal Shutdown

The KTZ8866 has Thermal Shutdown Protection which will turn off the backlight boost, all current sinks, LCD bias boost, inverting charge pump, and the LDO when the die temperature reaches or exceeds 150°C (typ). The I²C access is still available during Thermal Shutdown event, but TSD flag will be set in register 0x0F, this bit is real time reflection of TSD. When TSD is gone, the bit will be reset back to 0 automatically.

Device Functional Modes

Shutdown: The KTZ8866 is in shutdown when the HWEN pin is low. I²C writes are not recognized in shutdown.

Standby: After the HWEN pin is set high the KTZ8866 goes into standby mode. In standby mode, I²C writes are allowed but references, bias currents, the oscillator, LCD Bias, and backlight are all disabled to keep the quiescent supply current low.

Normal mode: Each of the main blocks of the KTZ8866 are independently controlled. For details on how to control each mode, see Tables 1 and 4.

Application Information

I²C Serial Data Bus

KTZ8866 supports the I²C bus protocol. A device that sends data onto the bus is defined as a transmitter and a device receiving data as a receiver. The device that controls the bus is called a master, whereas the devices controlled by the master are known as slaves. A master device must generate the serial clock (SCL), control bus access and generate START and STOP conditions to control the bus. KTZ8866 operates as a slave on the I²C bus. Within the bus specifications a standard mode (100kHz maximum clock rate) and a fast mode (400kHz maximum clock rate) are defined. KTZ8866 works in both modes. Connections to the bus are made through the open-drain I/O lines SDA and SCL.

The following bus protocol has been defined in Figure 5:

- Data transfer may be initiated only when the bus is not busy.
- During data transfer, the data line must remain stable whenever the clock line is HIGH. Changes in the data line while the clock line is high are interpreted as control signals.

Accordingly, the following bus conditions have been defined:

Bus Not Busy

Both data and clock lines remain HIGH.

Start Data Transfer

A change in the state of the data line, from HIGH to LOW, while the clock is HIGH, defines a START condition.

Stop Data Transfer

A change in the state of the data line, from LOW to HIGH, while the clock line is HIGH, defines the STOP condition.

Data Valid

The state of the data line represents valid data when, after a START condition, the data line is stable for the duration of the HIGH period of the clock signal. The data on the line must be changed during the LOW period of the clock signal. There is one clock pulse per bit of data.

Each data transfer is initiated with a START condition and terminated with a STOP condition. The number of data bytes transferred between START and STOP conditions are not limited and are determined by the master device. The information is transferred byte-wise and each receiver acknowledges with a ninth bit.

Acknowledge

Each receiving device, when addressed, is obliged to generate an acknowledge after the reception of each byte. The master device must generate an extra clock pulse that is associated with this acknowledge bit.

A device that acknowledges must pull down the SDA line during the acknowledge clock pulse in such a way that the SDA line is stable LOW during the HIGH period of the acknowledge-related clock pulse. Setup and hold times must also be taken into account.

Figure 5. Data Transfer on I²C Serial Bus

KTZ8866 7-bit slave device address is 0010001 binary (0x11h).

There are two kinds of I²C data transfer cycles: write cycle and read cycle.

I²C Write Cycle

For I²C write cycle, data is transferred from a master to a slave. The first byte transmitted is the 7-bit slave address plus one bit of '0' for write. Next follows a number of data bytes. The slave returns an acknowledge bit after each received byte. Data is transferred with the most significant bit (MSB) first. Figure 6 shows the sequence of the I²C write cycle.

Figure 6. I²C Write Cycle

I²C Write Cycle Steps:

- Master generates start condition.
- Master sends 7-bit slave address (0010001 for KTZ8866) and 1-bit data direction '0' for write.
- Slave sends acknowledge if the slave address is matched.
- Master sends 8-bit register address.
- Slave sends acknowledge.
- Master sends 8-bit data for that addressed register.
- Slave sends acknowledge.
- If master sends more data bytes, the register address will be incremented by one after each acknowledge.
- Master generate stop condition to finish the write cycle.

I²C Read Cycle

For I²C read cycle, data is transferred from a slave to a master. But to start the read cycle, master needs to write the register address first to define which register data to read. Figure 7 shows the steps of the I²C read cycle.

Figure 7. I²C Read Cycle

I²C Read Cycle Steps:

- Master generates start condition.
- Master sends 7-bit slave address (0010001 for KTZ8866) and 1-bit data direction '0' for write.
- Slave sends acknowledge if the slave address is matched.
- Master sends 8-bit register address.
- Slave sends acknowledge.
- Master generates repeated start condition.
- Master sends 7-bit slave address (0010001 for KTZ8866) and 1-bit data direction '1' for read.
- Slave sends acknowledge if the slave address is matched.
- Slave sends the data byte of that addressed register.
- If master sends acknowledge, the register address will be incremented by one after each acknowledge and the slave will continue to send the data for the updated addressed register.
- If master sends no acknowledge, the slave will stop sending the data.
- Master generate stop condition to finish the read cycle.

I²C Register Map

Table 5 summarizes KTZ8866's 21 I²C registers, their read/write settings and default values. They can be reset to default values by VIN power on reset, toggling HWEN or I²C software reset.

Table 5. I²C Register Map

Register Name	Address (Hex)	R/W	Default Value
Device ID	0x01	R	00100xxx

3:0	VOUTN_RAMP	0001	V_{OUTN} ramp time, high to low: 0000 = 456 μ s 0001 = 912μs (Default) 0010 = 1368 μ s 0011 = 1824 μ s 0100 = 2280 μ s 0101 = 2736 μ s 0110 = 3192 μ s 0111 = 3648 μ s 1000 = 4104 μ s 1001 = 4560 μ s 1010 = 5016 μ s 1011 = 5472 μ s 1100 = 5928 μ s 1101 = 6384 μ s 1110 = 6840 μ s 1111 = 7296 μ s

Note:

- For VOUTP_RAMP time, it is fixed slew rate ramp strategy, the ramp time value is given by assuming OUTP = 5.75V. If OUTP is set 5.5V and VOUTP_RAMP = 01, then actual ramp time will be 456*5.5/5.75 = 436μs.
- For VOUTN_RAMP time, it is fixed slew rate ramp strategy, the ramp time value is given by assuming OUTN = -5.75V. If OUTN is set -5.5V and VOUTN_RAMP = 0001, then actual ramp time will be 912*5.5/5.75 = 872μs.

2:0	PWM_RAMP_TIME	000	PWM Duty Cycle Transition Ramp Time 000 : 2ms (Default) 001 : 4ms 010 : 8ms 011 : 16ms 100 : 32ms 101 : 64ms 110 : 128ms 111 : 256ms The time in the table is defined as the time to change between 0% PWM duty cycle and 100% PWM duty cycle. The final PWM duty cycle transition time is the multiplication of the time in the table and the difference of the PWM duty cycle change.

Note: The PWM Dimming Transition Ramp Time in the table is defined as the time to change between minimum PWM duty cycle and the maximum PWM duty cycle. The final transition time is the multiplication of the time in the table and the change of the PWM duty cycle.

Capacitor Selection

Small size ceramic capacitors with low ESR are ideal for all applications. A 10μF input capacitor and a 4.7μF output capacitor are suggested. The voltage rating of these capacitors should exceed the maximum possible voltage at the corresponding pins, and these capacitors should be as close as possible to the IC. Table 25 shows the recommended capacitor vendors.

Table 25. Recommended Capacitor Vendors

Manufacturer	Website
Murata	www.murata.com
AVX	www.avx.com
Taiyo Yuden	www.t-yuden.com

Inductor Selection

An inductor of 4.7μH to 10μH with low DCR can be selected for the boost converter. To decide the current rating of the inductor required for the application, the following equation can be used to estimate the peak inductor current I_{PEAK} in continuous conduction mode (CCM):

$$I_{PEAK} = \frac{V_{OUT(MAX)} \times I_{OUT(MAX)}}{V_{IN(MIN)} \times \eta} + \frac{V_{IN(MIN)}}{2L \times F_{SW}} \times \left(1 - \frac{V_{IN(MIN)}}{V_{OUT(MAX)}} \right)$$

where $V_{OUT(MAX)}$ is the maximum output voltage, $V_{IN(MIN)}$ is the minimum input voltage, $I_{OUT(MAX)}$ is the maximum output current, F_{SW} is the boost converter's switching frequency, L is the inductor value, η is the boost converter's efficiency under that condition. Table 26 shows recommended inductors under different application conditions.

Table 26. Recommended Inductors

Value (μH)	Manufacturer	Inductor Part Number	DCR (Ω)	Saturation Current (A)	EIA Size (mm)
6.8	ECS INC.	ECS-MPI4040R4-6R8-R	0.091	3.2	4.0 x 4.0 x 1.8
6.8	CYNTEC	CMLB051H-6R8MS	0.125	3.4	5.4 x 5.2 x 1.8

Schottky Diode Selection

Using a schottky diode is recommended because of its low forward voltage drop and fast reverse recovery time. The average current rating of the schottky diode should exceed the maximum output current, and its peak current rating should exceed the peak inductor current. Its voltage rating should also exceed the OVP setting. Table 27 shows the recommended schottky diode.

Table 27. Recommended Schottky Diode

Application	Schottky Diode Part Number	Forward Voltage (V)	Forward Current (A)	Reverse Voltage (V)	Manufacturer
All	PMEG6010CEGWX	0.57	1	60	Nexperia

Capacitor Selection for Dual Output Bias

Small size ceramic capacitors with low ESR are ideal for all applications. A 10μF output capacitor at REG are suggested. Higher capacitor values can be used to improve the load transient response. The voltage rating of these capacitors should exceed the maximum possible voltage at the corresponding pins, and these capacitors should be as close as possible to the IC.

Flying Capacitor Selection for Bias

The charge pump needs an external flying capacitor. The minimum value for smartphone application is 4.7μF and 10μF for tablet application. Special care must be taken while choosing the flying capacitor as it will directly impact the output voltage accuracy and load regulation performance.

Inductor Selection for Dual Output Bias

An inductor in the range of 2.2μH to 10μH with low DCR can be selected for the boost converter. To estimate the inductance required for applications, calculate the maximum input average current as the following

$$I_{IN(MAX)} = \frac{V_{OUT} \cdot I_{OUT(MAX)}}{V_{IN} \cdot \eta}$$

Where, η is the converter efficiency and can be approximated as 90% for the typical case. In order to have smaller current ripple (to improve efficiency and minimize output voltage ripple), larger inductance will be required. If inductor ripple current needs to be less than 40% of the average input current, then

$$\Delta I_L = \frac{V_{IN} \cdot D \cdot T_S}{L} \leq 40\% \cdot \frac{V_{OUT} \cdot I_{OUT(MAX)}}{V_{IN} \cdot \eta}$$

Where duty cycle can be estimated as

$$D = \frac{V_{OUT} - V_{IN}}{V_{OUT}}$$

Then

$$\Delta I_L = \frac{V_{IN} \cdot (V_{OUT} - V_{IN}) \cdot T_S}{L \cdot V_{OUT}} \leq 40\% \cdot \frac{V_{OUT} \cdot I_{OUT(MAX)}}{V_{IN} \cdot \eta}$$

Therefore, the inductance can be calculated as

$$L \geq \frac{V_{IN}^2 \cdot (V_{OUT} - V_{IN}) \cdot \eta}{40\% \cdot V_{OUT}^2 \cdot I_{OUT(MAX)} \cdot f_S}$$

Where, f_S is the switching frequency of the boost converter.

Table 28. Recommended Inductor Part Numbers

Value (μH)	Manufacturer	Inductor Part Number	DCR (Ω)	Saturation Current (A)	EIA Size (mm)
2.2	Toko	DFE201612P-2R2M	0.12	2.1	2 x 1.6 x 1.0
2.2	CYCTEC	HMLQ25201T-2R2MSR	0.102	3	2.5 x 2.0 x 1.0

Recommended PCB Layout

PCB layout is very important for high frequency switching regulators in order to keep the loop stable and minimize noise. The input capacitor (C_{IN}) should be very close to the IC's VIN pin and PGND pin in order to get the best decoupling. The path between the inductor, LX pin, schottky diode and the output capacitor (C_{OUT}) should be kept as short as possible to minimize noise and ringing. To reduce power loss, the trace through the inductor, LX pin, schottky diode and C_{OUT} should be as short and wide as possible. Both input and output capacitors' GND terminals should be connected together on the PCB top layer and on the bottom layer GND plane.
