

Z8051 Series 8-Bit Microcontrollers

Z51F3220

Product Specification

PS029902-0212

PRELIMINARY

Warning: DO NOT USE THIS PRODUCT IN LIFE SUPPORT SYSTEMS.

LIFE SUPPORT POLICY

ZILOG'S PRODUCTS ARE NOT AUTHORIZED FOR USE AS CRITICAL COMPONENTS IN LIFE SUPPORT DEVICES OR SYSTEMS WITHOUT THE EXPRESS PRIOR WRITTEN APPROVAL OF THE PRESIDENT AND GENERAL COUNSEL OF ZILOG CORPORATION.

As used herein

Life support devices or systems are devices which (a) are intended for surgical implant into the body, or (b) support or sustain life and whose failure to perform when properly used in accordance with instructions for use provided in the labeling can be reasonably expected to result in a significant injury to the user. A critical component is any component in a life support device or system whose failure to perform can be reasonably expected to cause the failure of the life support device or system or to affect its safety or effectiveness.

Z51F3220

CMOS SINGLE-CHIP 8-BIT MICROCONTROLLER WITH 12-BIT A/D CONVERTER

1. Overview

1.1 Description

The Z51F3220 is advanced CMOS 8-bit microcontroller with 32k bytes of Flash. This is powerful microcontroller which provides a highly flexible and cost effective solution to many embedded control applications. This provides the following features : 32k bytes of Flash, 256 bytes of IIRAM, 768 bytes of XRAM , general purpose I/O, basic interval timer, watchdog timer, 8/16-bit timer/counter, 16-bit PPG output, 8-bit PWM output, 10-bit PWM output, watch timer, buzzer driving port, SPI, USI, 12-bit A/D converter, LCD driver, on-chip POR, LVR, LVI, on-chip oscillator and clock circuitry. The Z51F3220 also supports power saving modes to reduce power consumption.

Device Name	Flash	XRAM	IIRAM	ADC	I/O PORT	Package
Z51F3220FHX	32k bytes	768 bytes	256 bytes	16 channel	42	44-pin MQFP
Z51F3220SKX				12 channel	30	32-pin SOP

1.2 Features

- **CPU**
 - 8 Bit CISC Core (8051 Compatible)
- **ROM (Flash) Capacity**
 - 32k Bytes
 - Flash with self read/write capability
 - On chip debug and In-system programming (ISP)
 - Endurance : 100,000 times
- **256 Bytes IRAM**
- **768 Bytes XRAM**
 - (27 Bytes including LCD display RAM)
- **General Purpose I/O (GPIO)**
 - Normal I/O : 9 Ports
(P0[2:0], P5[5:0])
 - LCD shared I/O : 33 Ports
(P0[7:3], P1, P2, P3, P4)
- **Basic Interval Timer (BIT)**
 - 8Bit × 1ch
- **Watch Dog Timer (WDT)**
 - 8Bit × 1ch
 - 5kHz internal RC oscillator
- **Timer/ Counter**
 - 8Bit × 1ch (T0), 16Bit × 2ch (T1/T2)
 - 8Bit × 2ch (T3/T4) or 16 Bit × 1ch (T3)
- **Programmable Pulse Generation**
 - Pulse generation (by T1/T2)
 - 8Bit PWM (by T0)
 - 6-ch 10Bit PWM for Motor (by T4)
- **Watch Timer (WT)**
 - 3.91mS/0.25S/0.5S/1S/1M interval at 32.768kHz
- **Buzzer**
 - 8Bit × 1ch
- **SPI 2**
 - 8Bit × 1ch
- **USI0/1 (UART + SPI + I2C)**
 - 8Bit UART × 2ch, 8Bit SPI × 2ch and I2C × 2ch
- **12 Bit A/D Converter**
 - 16 Input channels
- **LCD Driver**
 - 21 Segments and 8 Common terminals
 - Internal or external resistor bias
 - 1/2, 1/3, 1/4, 1/5, 1/6 and 1/8 duty selectable
 - Resistor Bias and 16-step contrast control
- **Power On Reset**
 - Reset release level (1.4V)
- **Low Voltage Reset**
 - 14 level detect (1.60V/ 2.00V/ 2.10V/ 2.20V/
2.32V/ 2.44V/ 2.59V/ 2.75V/ 2.93V/ 3.14V/
3.38V/ 3.67V/ 4.00V/ 4.40V)
- **Low Voltage Indicator**
 - 13 level detect (2.00V/ 2.10V/ 2.20V/ 2.32V/
2.44V/ 2.59V/ 2.75V/ 2.93V/ 3.14V/ 3.38V/
3.67V/ 4.00V/ 4.40V)
- **Interrupt Sources**
 - External Interrupts
(EXINT0~7, EINT8, EINT10, EINT11, EINT12)
(12)
 - Timer(0/1/2/3/4) (5)
 - WDT (1)
 - BIT (1)
 - WT (1)
 - SPI 2 (1)
 - USI0/1 (6)
 - ADC (1)
- **Internal RC Oscillator**
 - Internal RC frequency: 16MHz ±0.5% (T_A= 25°C)
- **Power Down Mode**
 - STOP, IDLE mode
- **Operating Voltage and Frequency**
 - 1.8V ~ 5.5V (@32 ~ 38kHz with X-tal)
 - 1.8V ~ 5.5V (@0.4 ~ 4.2MHz with X-tal)
 - 2.7V ~ 5.5V (@0.4 ~ 10.0MHz with X-tal)
 - 3.0V ~ 5.5V (@0.4 ~ 12.0MHz with X-tal)
 - 1.8V ~ 5.5V (@0.5 ~ 8.0MHz with Internal RC)
 - 2.0V ~ 5.5V (@0.5 ~ 16.0MHz with Internal RC)
 - Voltage dropout converter included for core
- **Minimum Instruction Execution Time**
 - 125nS (@ 16MHz main clock)
 - 61μS (@t 32.768kHz sub clock)
- **Operating Temperature: - 40 ~ + 85°C**
- **Oscillator Type**
 - 0.4-12MHz Crystal or Ceramic for main clock
 - 32.768kHz Crystal for sub clock
- **Package Type**
 - 44 MQFP-1010
 - 32 SOP
 - Pb-free package

1.3 Ordering Information

Table 1-1 Ordering Information of Z51F3220

Device Name	ROM Size	IRAM Size	XRAM Size	Package
Z51F3220FNX	32k bytes Flash	256 bytes	768 bytes	44-pin MQFP
Z51F3220SKX				32-pin SOP

1.3.1 Part Number Suffix Designation

Zilog part numbers consist of a number of components, as indicated in the following example.

Example: Part number Z51F3220FNX is an 8-bit MCU with 32 KB of Flash memory and 1 KB of RAM in a 44-pin MQFP package and operating within a -40°C to $+85^{\circ}\text{C}$ temperature range. In accordance with RoHS standards, this device has been built using lead-free solder.

1.4 Development Tools

1.4.1 Compiler

We do not provide the compiler. Please contact the third parties.

The core of Z51F3220 is Mentor 8051. And, device ROM size is smaller than 32k bytes. Developer can use all kinds of third party's standard 8051 compiler.

1.4.2 OCD Emulator and Debugger

The OCD (On Chip Debug) emulator supports Zilog's 8051 series MCU emulation.

The OCD interface uses two-wire interfacing between PC and MCU which is attached to user's system. The OCD can read or change the value of MCU internal memory and I/O peripherals. And the OCD also controls MCU internal debugging logic, it means OCD controls emulation, step run, monitoring, etc.

The OCD Debugger program works on Microsoft-Windows NT, 2000, XP, Vista (32bit) operating system.

If you want to see more details, please refer to OCD debugger manual. You can download debugger S/W and manual from our web-site.

Connection:

- SCLK (Z51F3220 P01 port)
- SDATA (Z51F3220 P00 port)

OCD connector diagram: Connect OCD with user system

1.4.3 Programmer

Single programmer:

PGMplus USB: It programs MCU device directly.

OCD emulator: It can write code in MCU device too, because OCD debugging supports ISP (In System Programming).

It does not require additional H/W, except developer's target system.

Gang programmer:

It programs 8 MCU devices at once.

So, it is mainly used in mass production line.

Gang programmer is standalone type, it means it does not require host PC, after a program is downloaded from host PC to Gang programmer.

Figure 1.1 StandAlone Gang8 (for Mass Production)

2. Block Diagram

Figure 2.1 Block Diagram

NOTE) The P14–P17, P23–P25, P34–P37, and P43 are not in the 32-pin package.

3. Pin Assignment

Figure 3.1 Z51F3220 44MQFP-1010 Pin Assignment

NOTE) On On-Chip Debugging, ISP uses P0[1:0] pin as DSDA, DSCL.

Figure 3.2 Z51F3220 32SOP Pin Assignment

- NOTES) 1. On On-Chip Debugging, ISP uses P0[1:0] pin as DSDA, DSCL.
2. The P14-P17, P23-P25, P34-P37 and P43 pins should be selected as a push-pull output or an input with pull-up resistor by software control when the 32-pin package is used.

Top View: Shows a square package body with pin pitch D , body width E , and body length F . Pin numbers 1 through 23 are indicated around the perimeter.

Side View: Shows the profile of the package with lead height a , lead thickness b , and seating plane dimension e .

DETAIL A: A cross-sectional view of the lead showing a fillet radius of $R = 0.20 \text{ MIN}$, a lead angle of 1.6° , and a minimum lead thickness of 0.1 MIN . The seating plane is also indicated.

SYMBOLS	MIN.	NOM	MAX.
A	-	-	2.7
A1	0.25	-	0.50
A2	1.9	2.0	2.2
b		0.3 (TYP.)	
D	13.00	13.20	13.40
D1	9.9	10.00	10.10
E	13.00	13.20	13.40
E1	9.9	10.00	10.10
L	0.73	0.88	0.93
e		0.80 (TYP.)	
a	0	-	7
C	0.1	0.15	0.2

NOTES:

- JEDEC OUTLINE QFP-108 AA-1
- DATUM PLANE [B] IS LOCATED AT THE BOTTOM OF THE MOLD PARTING LINE COINCIDENT WITH WHERE THE LEAD EXITS THE BODY.
- DIMENSIONS D1 AND E1 DO NOT INCLUDE MOLD PROTRUSION. ALLOWABLE PROTRUSION IS 0.25 mm PER SIDE. DIMENSIONS D1 AND E1 DO INCLUDE MOLD MISMATCH AND ARE DETERMINED AT DATUM PLANE [B].
- DIMENSION b DOES NOT INCLUDE DAMBAR PROTRUSION.

UNIT : mm

5. Pin Description

Table 5-1 Normal Pin Description

PIN Name	I/O	Function	@RESET	Shared with
P00	I/O	Port 0 is a bit-programmable I/O port which can be configured as a schmitt-trigger input, a push-pull output, or an open-drain output. A pull-up resistor can be specified in 1-bit unit.	Input E	C3/DSDA
P01				T30/DSCL
P02 A				N0/AVREF/EINT0/T4O/PWM4AA
P03				SEG26/AN1/EINT1/PWM4AB
P04				SEG25/AN2/EINT2/PWM4BA
P05				SEG24/AN3/EINT3/PWM4BB
P06				SEG23/AN4/EINT4/PWM4CA
P07				SEG22/AN5/EINT5/PWM4CB
P10	I/O	Port 1 is a bit-programmable I/O port which can be configured as a schmitt-trigger input, a push-pull output, or an open-drain output. A pull-up resistor can be specified in 1-bit unit. The P14 – P17 are not in the 32-pin package.	Input SE	G14/AN13/RXD1/SCL1/MISO1
P11 SEG15				AN12/EINT12/T2O/PWM2O
P12 SEG16				AN11/EINT11/T1O/PWM1O
P13				SEG17/AN10/EC1/BUZO
P14				SEG18/AN9/MOSI2
P15				SEG19/AN8/MISO2
P16				SEG20/AN7/EINT7/SCK2
P17				SEG21/AN6/EINT6/SS2
P20	I/O	Port 2 is a bit-programmable I/O port which can be configured as an input, a push-pull output, or an open-drain output. A pull-up resistor can be specified in 1-bit unit. The P23 – P25 are not in the 32-pin package.	Input SE	G13/AN14/TXD1/SDA1/MOSI1
P21				SEG12/AN15/SCK1
P22				SEG11/SS1
P23				SEG10
P24				SEG9
P25				SEG8
P26				SEG7
P27				SEG6
P30	I/O	Port 3 is a bit-programmable I/O port which can be configured as an input, a push-pull output. A pull-up resistor can be specified in 1-bit unit. The P34 – P37 are only in the 44-pin package.	Input C	OM7/SEG5
P31				COM6/SEG4
P32				COM5/SEG3
P33				COM4/SEG2
P34				COM3/SEG1
P35				COM2/SEG0
P36				COM1
P37				COM0
P40	I/O	Port 4 is a bit-programmable I/O port which can be configured as an input, a push-pull output, or an open-drain output. A pull-up resistor can be specified in 1-bit unit. The P43 is only in the 44-pin package.	Input VLC3	/RXD0/SCL0/MISO0
P41				VLC2/TXD0/SDA0/MOSI0
P42				VLC1/SCK0
P43				VLC0/SS0

Table 5-1 Normal Pin Description (Continued)

PIN Name	I/O	Function @RESET		Shared with
RESETB	I/O	System reset pin with a pull-up resistor when it is selected as the RESETB by CONFIGURE OPTION	Input P	55
DSDA	I/O	On chip debugger data input/output ^(NOTE4,5) I	nput	P00/EC3
DSCL	I/O	On chip debugger clock input ^(NOTE4,5) In	put	P01/T3O
XIN	I/O	Main oscillator pins	Input	P51
XOUT				P50
SXIN	I/O	Sub oscillator pins	Input	P53/T0O/PWM0O
SXOUT				P54/EINT10
VDD, VSS	—	Power input pins	—	

- NOTES) 1. The P14–P17, P23–P25, P34–P37, and P43 are not in the 32-pin package.
2. The P55/RESETB pin is configured as one of the P55 and RESETB pin by the “CONFIGURE OPTION.”
3. If the P00/EC3/DSDA and P01/T3O/DSCL pins are connected to an emulator during the resetor power-on reset, the pins are automatically configured as the debugger pins.
4. The P00/EC3/DSDA and P01/T3O/DSCL pins are configured as inputs with internal pull-up resistor only during the reset or power-on reset.
5. The P50/XOUT, P51/XIN, P53/SXINT/T0O/PWM0O, and P54/SXOUT/EINT10 pins are configured as a function pin by software control.

7. Electrical Characteristics

7.1 Absolute Maximum Ratings

Table 7-1 Absolute Maximum Ratings

Parameter S	ymbol	Rating	Unit	Note
Supply Voltage	VDD	-0.3 ~ +6.5	V	—
Normal Voltage Pin	V _I	-0.3 ~ VDD+0.3	V	Voltage on any pin with respect to VSS
	V _O	-0.3 ~ VDD+0.3	V	
	I _{OH} -10		mA	
	ΣI _{OH} -80		mA	Maximum current (ΣI _{OH})
	I _{OL}	60	mA	Maximum current sunk by (I _{OL} per I/O pin)
	ΣI _{OL} 120		mA	Maximum current (ΣI _{OL})
Total Power Dissipation	P _T 600		mW	—
Storage Temperature	T _{STG}	-65 ~ +150	°C	—

NOTE) Stresses beyond those listed under “Absolute Maximum Ratings” may cause permanent damage to the device. This is a stress rating only and functional operation of the device at any other conditions beyond those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

7.2 Recommended Operating Conditions

Table 7-2 Recommended Operating Conditions

(T_A= -40°C ~ +85°C)

Parameter	Symbol	Con	ditions	MIN	TYP	MAX	Unit
Operating Voltage	VDD	f _X = 32 ~ 38kHz	SX-tal	1.8	—	5.5	V
		f _X = 0.4 ~ 4.2MHz	X-tal	1.8 ~ 5.5			
		f _X = 0.4 ~ 10.0MHz		2.7 ~ 5.5			
		f _X = 0.4 ~ 12.0MHz		3.0 ~ 5.5			
		f _X = 0.5 ~ 8.0MHz	Internal RC	1.8 ~ 5.5			
		f _X = 0.5 ~ 16.0MHz		2.0 ~ 5.5			
Operating Temperature	T _{OPR}	V	DD= 1.8 ~ 5.5V	-40	—	85	°C

7.3 A/D Converter Characteristics

Table 7-3 A/D Converter Characteristics

(T_A= -40°C ~ +85°C, VDD= 1.8V ~ 5.5V, VSS= 0V)

Parameter Sy	mbol	Conditions	MIN	TYP	MAX	Unit
Resolution –		–	–	12	–	bit
Integral Linear Error	ILE	AVREF= 2.7V – 5.5V fx= 8MHz	–	–	±3	LSB
Differential Linearity Error	DLE –		–	–	±1	
Zero Offset Error	ZOE		–	–	±3	
Full Scale Error	FSE		–	–	±3	
Conversion Time	t _{CON} 12b	12 bit resolution, 8MHz	20	–	–	μS
Analog Input Voltage	V _{AN} –		VSS	–	AVREF	V
Analog Reference Voltage	AVREF –		1.8	–	VDD	
Analog Input Leakage Current	I _{AN} AVRE	F= 5.12V	–	–	2	μA
ADC Operating Current	I _{ADC}	Enable	– 1		2	mA
		Disable –		–	0.1	μA

NOTES) 1. Zero offset error is the difference between 000000000 and the converted output for zero input voltage (VSS).

2. Full scale error is the difference between 111111111 and the converted output for full-scale input voltage (AVREF).

7.4 Power-On Reset Characteristics

Table 7-4 Power-on Reset Characteristics

(T_A= -40°C ~ +85°C, VDD= 1.8V ~ 5.5V, VSS= 0V)

7.23 Typical Characteristics

These graphs and tables provided in this section are only for design guidance and are not tested or guaranteed. In graphs or tables some data are out of specified operating range (e.g. out of specified VDD range). This is only for information and devices are guaranteed to operate properly only within the specified range.

The data presented in this section is a statistical summary of data collected on units from different lots over a period of time. "Typical" represents the mean of the distribution while "max" or "min" represents (mean + 3 σ) and (mean - 3 σ) respectively where σ is standard deviation.

8. Memory

The Z51F3220 addresses two separate address memory stores: Program memory and Data memory. The logical separation of Program and Data memory allows Data memory to be accessed by 8-bit addresses, which makes the 8-bit CPU access the data memory more rapidly. Nevertheless, 16-bit Data memory addresses can also be generated through the DPTR register.

Z51F3220 provides on-chip 32k bytes of the ISP type flash program memory, which can be read and written to. Internal data memory (IRAM) is 256 bytes and it includes the stack area. External data memory (XRAM) is 768 bytes and it includes 27 bytes of LCD display RAM.

8.1 Program Memory

A 16-bit program counter is capable of addressing up to 64k bytes, but this device has just 32k bytes program memory space.

Figure 8-1 shows the map of the lower part of the program memory. After reset, the CPU begins execution from location 0000H. Each interrupt is assigned a fixed location in program memory. The interrupt causes the CPU to jump to that location, where it commences execution of the service routine. External interrupt 11, for example, is assigned to location 000BH. If external interrupt 11 is going to be used, its service routine must begin at location 000BH. If the interrupt is not going to be used, its service location is available as general purpose program memory. If an interrupt service routine is short enough (as is often the case in control applications), it can reside entirely within that 8 byte interval. Longer service routines can use a jump instruction to skip over subsequent interrupt locations, if other interrupts are in use.

- 32k Bytes Including Interrupt Vector Region

Figure 8.1 Program Memory

8.2 Data Memory

Figure 8-2 shows the internal data memory space available.

Figure 8.2 Data Memory Map

The internal data memory space is divided into three blocks, which are generally referred to as the lower 128 bytes, upper 128 bytes, and SFR space.

Internal data memory addresses are always one byte wide, which implies an address space of only 256 bytes. However, in fact the addressing modes for internal RAM can accommodate up to 384 bytes by using a simple trick. Direct addresses higher than 7FH access one memory space and indirect addresses higher than 7FH access a different memory space. Thus Figure 8-2 shows the upper 128 bytes and SFR space occupying the same block of addresses, 80H through FFH, although they are physically separate entities.

The lower 128 bytes of RAM are present in all 8051 devices as mapped in Figure 8-3. The lowest 32 bytes are grouped into 4 banks of 8 registers. Program instructions call out these registers as R0 through R7. Two bits in the Program Status Word select which register bank is in use. This allows more efficient use of code space, since register instructions are shorter than instructions that use direct addressing.

The next 16 bytes above the register banks form a block of bit-addressable memory space. The 8051 instruction set includes a wide selection of single-bit instructions, and the 128 bits in this area can be directly addressed by these instructions. The bit addresses in this area are 00H through 7FH.

All of the bytes in the lower 128 bytes can be accessed by either direct or indirect addressing. The upper 128 bytes RAM can only be accessed by indirect addressing. These spaces are used for data RAM and stack.

Figure 8.3 Lower 128 Bytes RAM

8.3 XRAM Memory

Z51F3220 has 768 bytes XRAM. This area has no relation with RAM/Flash. It can be read and written to through SFR with 8-bit unit.

Figure 8.4 XDATA Memory Area

9. I/O Ports

9.1 I/O Ports

The Z51F3220 has ten groups of I/O ports (P0 ~ P5). Each port can be easily configured by software as I/O pin, internal pull up and open-drain pin to meet various system configurations and design requirements. Also P0 includes function that can generate interrupt according to change of state of the pin.

9.2 Port Register

9.2.1 Data Register (Px)

Data Register is a bidirectional I/O port. If ports are configured as output ports, data can be written to the corresponding bit of the Px. If ports are configured as input ports, the data can be read from the corresponding bit of the Px.

9.2.2 Direction Register (PxIO)

Each I/O pin can be independently used as an input or an output through the PxIO register. Bits cleared in this register will make the corresponding pin of Px to input mode. Set bits of this register will make the pin to output mode. Almost bits are cleared by a system reset, but some bits are set by a system reset.

9.2.3 Pull-up Resistor Selection Register (PxPU)

The on-chip pull-up resistor can be connected to I/O ports individually with a pull-up resistor selection register (PxPU). The pull-up register selection controls the pull-up resistor enable/disable of each port. When the corresponding bit is 1, the pull-up resistor of the pin is enabled. When 0, the pull-up resistor is disabled. All bits are cleared by a system reset.

9.2.4 Open-drain Selection Register (PxOD)

There are internally open-drain selection registers (PxOD) for P0 ~ P4 and a bit for P5. The open-drain selection register controls the open-drain enable/disable of each port. Almost ports become push-pull by a system reset, but some ports become open-drain by a system reset.

9.2.5 Debounce Enable Register (PxDB)

P0[7:2], P1[2:1], P1[7:6], P52 and P54 support debounce function. Debounce clocks of each ports are $fx/1$, $fx/4$, and $fx/4096$.

9.2.6 Port Function Selection Register (PxFSR)

These registers define alternative functions of ports. Please remember that these registers should be set properly for alternative port function. A reset clears the PxFSR register to '00H', which makes all pins to normal I/O ports.

9.2.7 Register Map

9.3 P0 Port

9.3.1 P0 Port Description

P0 is 8-bit I/O port. P0 control registers consist of P0 data register (P0), P0 direction register (P0IO), debounce enable register (P0DB), P0 pull-up resistor selection register (P0PU), and P0 open-drain selection register (P0OD). Refer to the port function selection registers for the P0 function selection.

NOTES) 1. If the same level is not detected on enabled pin three or four times in a row at the sampling clock, the signal is eliminated as noise.

2. A pulse level should be input for the duration of 3 clock or more to be actually detected as a valid edge.

3. The port debounce is automatically disabled at stop mode and recovered after stop mode release.

9.4 P1 Port

9.4.1 P1 Port Description

P1 is 8-bit I/O port. P1 control registers consist of P1 data register (P1), P1 direction register (P1IO), debounce enable register (P15DB), P1 pull-up resistor selection register (P1PU), and P1 open-drain selection register (P1OD) . Refer to the port function selection registers for the P1 function selection.

- NOTES) 1. If the same level is not detected on enabled pin three or four times in a row at the sampling clock, the signal is eliminated as noise.
2. A pulse level should be input for the duration of 3 clock or more to be actually detected as a valid edge.
3. The port debounce is automatically disabled at stop mode and recovered after stop mode release.
4. Refer to the port 0 debounce enable register (P0DB) for the debounce clock of port 1 and port 5.

9.5 P2 Port

9.5.1 P2 Port Description

P2 is 8-bit I/O port. P2 control registers consist of P2 data register (P2), P2 direction register (P2IO), P2 pull-up resistor selection register (P2PU) and P2 open-drain selection register (P2OD). Refer to the port function selection registers for the P2 function selection.

10. Interrupt Controller

10.1 Overview

The Z51F3220 supports up to 23 interrupt sources. The interrupts have separate enable register bits associated with them, allowing software control. They can also have four levels of priority assigned to them. The non-maskable interrupt source is always enabled with a higher priority than any other interrupt source, and is not controllable by software. The interrupt controller has following features:

- Receive the request from 23 interrupt source
- 6 group priority
- 4 priority levels
- Multi Interrupt possibility
- If the requests of different priority levels are received simultaneously, the request of higher priority level is served first.
- Each interrupt source can be controlled by EA bit and each IEx bit
- Interrupt latency: 3~9 machine cycles in single interrupt system

The non-maskable interrupt is always enabled. The maskable interrupts are enabled through four pair of interrupt enable registers (IE, IE1, IE2, IE3). Each bit of IE, IE1, IE2, IE3 register individually enables/disables the corresponding interrupt source. Overall control is provided by bit 7 of IE (EA). When EA is set to '0', all interrupts are disabled: when EA is set to '1', interrupts are individually enabled or disabled through the other bits of the interrupt enable registers. The EA bit is always cleared to '0' jumping to an interrupt service vector and set to '1' executing the [RETI] instruction. The Z51F3220 supports a four-level priority scheme. Each maskable interrupt is individually assigned to one of four priority levels according to IP and IP1.

Default interrupt mode is level-trigger mode basically, but if needed, it is possible to change to edge-trigger mode. Table 10-1 shows the Interrupt Group Priority Level that is available for sharing interrupt priority. Priority of a group is set by two bits of interrupt priority registers (one bit from IP, another one from IP1). Interrupt service routine serves higher priority interrupt first. If two requests of different priority levels are received simultaneously, the request of higher priority level is served prior to the lower one.

Table 10-1 Interrupt Group Priority Level

Interrupt Group	Highest Lowest				
0 (Bit0)	Interrupt 0	Interrupt 6	Interrupt 12	Interrupt 18	Highest Lowest
1 (Bit1)	Interrupt 1	Interrupt 7	Interrupt 13	Interrupt 19	
2 (Bit2)	Interrupt 2	Interrupt 8	Interrupt 14	Interrupt 20	
3 (Bit3)	Interrupt 3	Interrupt 9	Interrupt 15	Interrupt 21	
4 (Bit4)	Interrupt 4	Interrupt 10	Interrupt 16	Interrupt 22	
5 (Bit5)	Interrupt 5	Interrupt 11	Interrupt 17	Interrupt 23	

10.2 External Interrupt

The external interrupt on INT0, INT1, INT5, INT6 and INT11 pins receive various interrupt request depending on the external interrupt polarity 0 high/low register (EIPOL0H/L) and external interrupt polarity 1 register (EIPOL1) as shown in Figure 10.1. Also each external interrupt source has enable/disable bits. The External interrupt flag 0 register (EIFLAG0) and external interrupt flag 1 register (EIFLAG1) provides the status of external interrupts.

Figure 10.1 External Interrupt Description

10.3 Block Diagram

Figure 10.2 Block Diagram of Interrupt

- NOTES) 1. The release signal for stop/idle mode may be generated by all interrupt sources which are enabled without reference to the priority level.
2. An interrupt request is delayed while data are written to IE, IE1, IE2, IE3, IP, IP1, and PCON register.

10.4 Interrupt Vector Table

The interrupt controller supports 24 interrupt sources as shown in the Table 10-2. When interrupt is served, long call instruction (LCALL) is executed and program counter jumps to the vector address. All interrupt requests have their own priority order.

Table 10-2 Interrupt Vector Address Table

Interrupt Source	Symbol	Interrupt Enable Bit	Polarity	Mask	Vector Address
Hardware Reset	RESETB	0 0	0	Non-Maskable	0000H
External Interrupt 10	INT0	IE.0	1	Maskable	0003H
External Interrupt 11	INT1	IE.1	2	Maskable	000BH
USI1 I2C Interrupt	INT2	IE.2	3	Maskable	0013H

USI1 Tx Interrupt	INT4	IE.4	5	Maskable	0023H
External Interrupt 0 - 7	INT5	IE.5	6	Maskable	002BH
External Interrupt 8	INT6	IE1.0	7	Maskable	0033H
-	INT7	IE1.1	8	Maskable	003BH
USI0 I2C Interrupt	INT8	IE1.2	9	Maskable	0043H
USI0 Rx Interrupt	INT9	IE1.3	10	Maskable	004BH
USI0 Tx Interrupt	INT10	IE1.4	11	Maskable	0053H
External Interrupt 12	INT11	IE1.5	12	Maskable	005BH
T0 Overflow Interrupt	INT12	IE2.0	13	Maskable	0063H
T0 Match Interrupt	INT13	IE2.1	14	Maskable	006BH
T1 Match Interrupt	INT14	IE2.2	15	Maskable	0073H
T2 Match Interrupt	INT15	IE2.3	16	Maskable	007BH
T3 Match Interrupt	INT16	IE2.4	17	Maskable	0083H
T4 Interrupt	INT17	IE2.5	18	Maskable	008BH
ADC Interrupt	INT18	IE3.0	19	Maskable	0093H
SPI 2 Interrupt	INT19	IE3.1	20	Maskable	009BH
WT Interrupt	INT20	IE3.2	21	Maskable	00A3H
WDT Interrupt	INT21	IE3.3	22	Maskable	00ABH
BIT Interrupt	INT22	IE3.4	23	Maskable	00B3H
-	INT23	IE3.5	24	Maskable	00BBH

For maskable interrupt execution, EA bit must set '1' and specific interrupt must be enabled by writing '1' to associated bit in the IEx. If an interrupt request is received, the specific interrupt request flag is set to '1'. And it remains '1' until CPU accepts interrupt. If the interrupt is served, the interrupt request flag will be cleared automatically.

10.5 Interrupt Sequence

An interrupt request is held until the interrupt is accepted or the interrupt latch is cleared to '0' by a reset or an instruction. Interrupt acceptance always generates at last cycle of the instruction. So instead of fetching the current instruction, CPU executes internally LCALL instruction and saves the PC at stack. For the interrupt service routine, the interrupt controller gives the address of LJMP instruction to CPU. Since the end of the execution of current instruction, it needs 3~9 machine cycles to go to the interrupt service routine. The interrupt service task is terminated by the interrupt return instruction [RETI]. Once an interrupt request is generated, the following process is performed.

Figure 10.3 Interrupt Vector Address Table

10.6 Effective Timing after Controlling Interrupt Bit

Case a) Control Interrupt Enable Register (IE, IE1, IE2, IE3)

Figure 10.4 Effective Timing of Interrupt Enable Register

Case b) Interrupt flag Register

Figure 10.5 Effective Timing of Interrupt Flag Register

10.7 Multi Interrupt

If two requests of different priority levels are received simultaneously, the request of higher priority level is served first. If more than one interrupt request are received, the interrupt polling sequence determines which request is served first by hardware. However, for special features, multi-interrupt processing can be executed by software.

Figure 10.6 Effective Timing of Interrupt

Figure 10.6 shows an example of multi-interrupt processing. While INT1 is served, INT0 which has higher priority than INT1 is occurred. Then INT0 is served immediately and then the remain part of INT1 service routine is executed. If the priority level of INT0 is same or lower than INT1, INT0 will be served after the INT1 service has completed.

An interrupt service routine may be only interrupted by an interrupt of higher priority and, if two interrupts of different priority occur at the same time, the higher level interrupt will be served first. An interrupt cannot be interrupted by another interrupt of the same or a lower priority level. If two interrupts of the same priority level occur simultaneously, the service order for those interrupts is determined by the scan order.

10.11 Interrupt Timing

Figure 10.10 Timing Chart of Interrupt Acceptance and Interrupt Return Instruction

Interrupt sources are sampled at the last cycle of a command. If an interrupt source is detected the lower 8-bit of interrupt vector (INT_VEC) is decided. M8051W core makes interrupt acknowledge at the first cycle of a command, and executes long call to jump to interrupt service routine.

NOTE) command cycle CLPx: L=Last cycle, 1=1st cycle or 1st phase, 2=2nd cycle or 2nd phase

10.12 Interrupt Register Overview

10.12.1 Interrupt Enable Register (IE, IE1, IE2, IE3)

Interrupt enable register consists of global interrupt control bit (EA) and peripheral interrupt control bits. Total 24 peripherals are able to control interrupt.

10.12.2 Interrupt Priority Register (IP, IP1)

The 24 interrupts are divided into 6 groups which have each 4 interrupt sources. A group can be assigned 4 levels interrupt priority using interrupt priority register. Level 3 is the highest priority, while level 0 is the lowest priority. After a reset IP and IP1 are cleared to '00H'. If interrupts have the same priority level, lower number interrupt is served first.

10.12.3 External Interrupt Flag Register (EIFLAG0, EIFLAG1)

The external interrupt flag 0 register (EIFLAG0) and external interrupt flag 1 register (EIFLAG1) are set to '1' when the external interrupt generating condition is satisfied. The flag is cleared when the interrupt service routine is executed. Alternatively, the flag can be cleared by writing '0' to it.

10.12.4 External Interrupt Polarity Register (EIPOL0L, EIPOL0H, EIPOL1)

The external interrupt polarity 0 high/low register (EIPOL0H/L) and external interrupt polarity 1 register (EIPOL1) determines which type of rising/falling/both edge interrupt. Initially, default value is no interrupt at any edge.

10.12.5 Register Map

10.13 Interrupt Register Description

The interrupt register is used for controlling interrupt functions. Also it has external interrupt control registers. The interrupt register consists of interrupt enable register (IE), interrupt enable register 1 (IE1), interrupt enable register 2 (IE2) and interrupt enable register 3 (IE3). For external interrupt, it consists of external interrupt flag 0 register (EIFLAG0), external interrupt polarity 0 high/low register (EIPOL0H/L), external interrupt flag 1 register (EIFLAG1) and external interrupt polarity 1 register (EIPOL1).

11. Peripheral Hardware

11.1 Clock Generator

11.1.1 Overview

As shown in Figure 11.1, the clock generator produces the basic clock pulses which provide the system clock to be supplied to the CPU and the peripheral hardware. It contains main/sub-frequency clock oscillator. The main/sub clock operation can be easily obtained by attaching a crystal between the XIN/SXIN and XOUT/SXOUT pin, respectively. The main/sub clock can be also obtained from the external oscillator. In this case, it is necessary to put the external clock signal into the XIN/SXIN pin and open the XOUT/SXOUT pin. The default system clock is 1MHz INT-RC Oscillator and the default division rate is eight. In order to stabilize system internally, it is used 1MHz INT-RC oscillator on POR.

- Calibrated Internal RC Oscillator (16 MHz)
 - . INT-RC OSC/1 (16 MHz)
 - . INT-RC OSC/2 (8 MHz)
 - . INT-RC OSC/4 (4 MHz)
 - . INT-RC OSC/8 (2 MHz)
 - . INT-RC OSC/16 (1 MHz, Default system clock)
 - . INT-RC OSC/32 (0.5 MHz)
- Main Crystal Oscillator (0.4~12 MHz)
- Sub Crystal Oscillator (32.768 kHz)
- Internal WDTRC Oscillator (5 kHz)

11.2 Basic Interval Timer

11.2.1 Overview

The Z51F3220 has one 8-bit basic interval timer that is free-run and can't stop. Block diagram is shown in Figure 11.2. In addition, the basic interval timer generates the time base for watchdog timer counting. It also provides a basic interval timer interrupt (BITIFR).

The Z51F3220 has these basic interval timer (BIT) features:

- During Power On, BIT gives a stable clock generation time
- On exiting Stop mode, BIT gives a stable clock generation time
- As timer function, timer interrupt occurrence

11.3 Watch Dog Timer

11.3.1 Overview

The watchdog timer rapidly detects the CPU malfunction such as endless looping caused by noise or something like that, and resumes the CPU to the normal state. The watchdog timer signal for malfunction detection can be used as either a CPU reset or an interrupt request. When the watchdog timer is not being used for malfunction detection, it can be used as a timer to generate an interrupt at fixed intervals. It is possible to use free running 8-bit timer mode (WDTRSON='0') or watch dog timer mode (WDTRSON='1') as setting WDTCR[6] bit. If WDTCR[5] is written to '1', WDT counter value is cleared and counts up. After 1 machine cycle, this bit is cleared to '0' automatically. The watchdog timer consists of 8-bit binary counter and the watchdog timer data register. When the value of 8-bit binary counter is equal to the 8 bits of WDTCNT, the interrupt request flag is generated. This can be used as Watchdog timer interrupt or reset of CPU in accordance with the bit WDTRSON.

The input clock source of watch dog timer is the BIT overflow. The interval of watchdog timer interrupt is decided by BIT overflow period and WDTDR set value. The equation can be described as

$$\text{WDT Interrupt Interval} = (\text{BIT Interrupt Interval}) \times (\text{WDTDR Value} + 1)$$

 0 WDT Interrupt no generation
 1 WDT Interrupt generation

11.4 Watch Timer

11.4.1 Overview

The watch timer has the function for RTC (Real Time Clock) operation. It is generally used for RTC design. The internal structure of the watch timer consists of the clock source select circuit, timer counter circuit, output select circuit, and watch timer control register. To operate the watch timer, determine the input clock source, output interval, and set WTEN to '1' in watch timer control register (WTCR). It is able to execute simultaneously or individually. To stop or reset WT, clear the WTEN bit in WTCR register. Even if CPU is STOP mode, sub clock is able to be so alive that WT can continue the operation. The watch timer counter circuits may be composed of 21-bit counter which contains low 14-bit with binary counter and high 7-bit counter in order to raise resolution. In WTDR, it can control WT clear and set interval value at write time, and it can read 7-bit WT counter value at read time.

The watch timer supplies the clock frequency for the LCD driver (f_{LCD}). Therefore, if the watch timer is disabled, the LCD driver controller does not operate.

11.4.4 Watch Timer Register Description

The watch timer register consists of watch timer counter register (WTCNT), watch timer data register (WTDR), and watch timer control register (WTCR). As WTCR is 6-bit writable/ readable register, WTCR can control the clock source (WTCK[1:0]), interrupt interval (WTIN[1:0]), and function enable/disable (WTEN). Also there is WT interrupt flag bit (WTIFR).

11.4.5 Register Description for Watch Timer

NOTE) f_x – System clock frequency (Where $f_x = 4.19\text{MHz}$)

f_{SUB} – Sub clock oscillator frequency (32.768kHz)

f_{WCK} – Selected Watch timer clock

f_{LCD} – LCD frequency (Where $f_x = 4.19\text{MHz}$, $WTCK[1:0] = '10'$; $f_{LCD} = 1024\text{Hz}$)

11.5 Timer 0

11.5.1 Overview

The 8-bit timer 0 consists of multiplexer, timer 0 counter register, timer 0 data register, timer 0 capture data register and timer 0 control register (T0CNT, T0DR, T0CDR, T0CR).

It has three operating modes:

- 8-bit timer/counter mode
- 8-bit PWM output mode
- 8-bit capture mode

The timer/counter 0 can be clocked by an internal or an external clock source (EC0). The clock source is selected by clock selection logic which is controlled by the clock selection bits (T0CK[2:0]).

- TIMER 0 clock source: $f_x/2$, 4, 8, 32, 128, 512, 2048 and EC0

In the capture mode, by EINT10, the data is captured into input capture data register (T0CDR). In timer/counter mode, whenever counter value is equal to T0DR, T0O port toggles. Also the timer 0 outputs PWM waveform through PWM0O port in the PWM mode.

Table 11-5 Timer 0 Operating Modes

T0EN T0	MS[1:0]	T0CK[2:0]	Timer 0
1	00	XXX	8 Bit Timer/Counter Mode
1	01	XXX	8 Bit PWM Mode
1	1X	XXX	8 Bit Capture Mode

11.5.2 8-Bit Timer/Counter Mode

The 8-bit timer/counter mode is selected by control register as shown in Figure 11.6.

The 8-bit timer have counter and data register. The counter register is increased by internal or external clock input. Timer 0 can use the input clock with one of 2, 4, 8, 32, 128, 512 and 2048 prescaler division rates (T0CK[2:0]). When the value of T0CNT and T0DR is identical in timer 0, a match signal is generated and the interrupt of Timer 0 occurs. T0CNT value is automatically cleared by match signal. It can be also cleared by software (T0CC).

The external clock (EC0) counts up the timer at the rising edge. If the EC0 is selected as a clock source by T0CK[2:0], EC0 port should be set to the input port by P52IO bit.

Figure 11.6 8-Bit Timer/Counter Mode for Timer 0

Figure 11.7 8-Bit Timer/Counter 0 Example

11.5.3 8-Bit PWM Mode

The timer 0 has a high speed PWM (Pulse Width Modulation) function. In PWM mode, T0O/PWM00 pin outputs up to 8-bit resolution PWM output. This pin should be configured as a PWM output by setting the T0O/PWM00 function by P5FSR[4:3] bits. In the 8-bit timer/counter mode, a match signal is generated when the counter value is identical to the value of T0DR. When the value of T0CNT and T0DR is identical in timer 0, a match signal is generated and the interrupt of timer 0 occurs. In PWM mode, the match signal does not clear the counter. Instead, it runs continuously, overflowing at “FFH”, and then continues incrementing from “00H”. The timer 0 overflow interrupt is generated whenever a counter overflow occurs. T0CNT value is cleared by software (T0CC) bit.

Figure 11.8 8-Bit PWM Mode for Timer 0

Figure 11.9 PWM Output Waveforms in PWM Mode for Timer 0

11.5.4 8-Bit Capture Mode

The timer 0 capture mode is set by T0MS[1:0] as '1x'. The clock source can use the internal/external clock. Basically, it has the same function as the 8-bit timer/counter mode and the interrupt occurs when T0CNT is equal to T0DR. T0CNT value is automatically cleared by match signal and it can be also cleared by software (T0CC).

This timer interrupt in capture mode is very useful when the pulse width of captured signal is wider than the maximum period of timer.

The capture result is loaded into T0CDR. In the timer 0 capture mode, timer 0 output (T0O) waveform is not available.

According to EIPOL1 registers setting, the external interrupt EINT10 function is chosen. Of course, the EINT10 pin must be set to an input port.

T0CDR and T0DR are in the same address. In the capture mode, reading operation reads T0CDR, not T0DR and writing operation will update T0DR.

11.6 Timer 1

11.6.1.1 Overview

The 16-bit timer 1 consists of multiplexer, timer 1 A data register high/low, timer 1 B data register high/low and timer 1 control register high/low (T1ADRH, T1ADRL, T1BDRH, T1BDRL, T1CRH, T1CRL).

It has four operating modes:

- 16-bit timer/counter mode
- 16-bit capture mode
- 16-bit PPG output mode (one-shot mode)
- 16-bit PPG output mode (repeat mode)

The timer/counter 1 can be clocked by an internal or an external clock source (EC1). The clock source is selected by clock selection logic which is controlled by the clock selection bits (T1CK[2:0]).

- TIMER 1 clock source: $f_x/1, 2, 4, 8, 64, 512, 2048$ and EC1

In the capture mode, by EINT11, the data is captured into input capture data register (T1BDRH/T1BDRL). Timer 1 outputs the comparison result between counter and data register through T1O port in timer/counter mode. Also Timer 1 outputs PWM wave form through PWM1O port in the PPG mode.

Table 11-7 Timer 1 Operating Modes

T1EN P	1FSRL[5:4]	T1MS[1:0] T1	CK[2:0]	Timer 1
1	11	00	XXX	16 Bit Timer/Counter Mode
1	00	01	XXX	16 Bit Capture Mode
1 11		10	XXX	16 Bit PPG Mode (one-shot mode)
1 11		11	XXX	16 Bit PPG Mode (repeat mode)

11.6.2 16-Bit Timer/Counter Mode

The 16-bit timer/counter mode is selected by control register as shown in Figure 11.14.

The 16-bit timer have counter and data register. The counter register is increased by internal or external clock input. Timer 1 can use the input clock with one of 1, 2, 4, 8, 64, 512 and 2048 prescaler division rates (T1CK[2:0]). When the value of T1CNTH, T1CNTL and the value of T1ADRH, T1ADRL are identical in Timer 1 respectively, a match signal is generated and the interrupt of Timer 1 occurs. The T1CNTH, T1CNTL value is automatically cleared by match signal. It can be also cleared by software (T1CC).

The external clock (EC1) counts up the timer at the rising edge. If the EC1 is selected as a clock source by T1CK[2:0], EC1 port should be set to the input port by P13IO bit.

Figure 11.14 16-Bit Timer/Counter Mode for Timer 1

Figure 11.15 16-Bit Timer/Counter 1 Example

The 16-bit timer 1 capture mode is set by T1MS[1:0] as '01'. The clock source can use the internal/external clock. Basically, it has the same function as the 16-bit timer/counter mode and the interrupt occurs when T1CNTH/T1CNTL is equal to T1ADRH/T1ADRL. The T1CNTH, T1CNTL values are automatically cleared by match signal. It can be also cleared by software (T1CC).

The capture result is loaded into T1BDRH/T1BDRL.

Figure 11.17 Input Capture Mode Operation for Timer 1

Figure 11.18 Express Timer Overflow in Capture Mode

11.6.4 16-Bit PPG Mode

The timer 1 has a PPG (Programmable Pulse Generation) function. In PPG mode, T1O/PWM1O pin outputs up to 16-bit resolution PWM output. This pin should be configured as a PWM output by setting P1FSRL[5:4] to '11'. The period of the PWM output is determined by the T1ADRH/T1ADRL. And the duty of the PWM output is determined by the T1BDRH/T1BDRL.

NOTE) The T1EN is automatically cleared to logic "0" after one pulse is generated at a PPG one-shot mode.

11.7 Timer 2

11.7.1.1 Overview

The 16-bit timer 2 consists of multiplexer, timer 2 A data high/low register, timer 2 B data high/low register and timer 2 control high/low register (T2ADRH, T2ADRL, T2BDRH, T2BDRL, T2CRH, T2CRL).

It has four operating modes:

- 16-bit timer/counter mode
- 16-bit capture mode
- 16-bit PPG output mode (one-shot mode)
- 16-bit PPG output mode (repeat mode)

The timer/counter 2 can be divided clock of the system clock selectd from prescaler output and T1 A Match (timer 1 A match signal). The clock source is selected by clock selection logic which is controlled by the clock selection bits (T2CK[2:0]).

- TIMER 2 clock source: $f_x/1$, 2, 4, 8, 32, 128, 512 and T1 A Match

In the capture mode, by EINT12, the data is captured into input capture data register (T2BDRH/T2BDRL). In timer/counter mode, whenever counter value is equal to T2ADRH/L, T2O port toggles. Also the timer 2 outputs PWM wave form to PWM2O port in the PPG mode.

Table 11-9 Timer 2 Operating Modes

T2EN P1	SRL [3:2]	T2MS[1:0]	T2CK[2:0]	Timer 2
1	11	00	XXX	16 Bit Timer/Counter Mode
1	00	01	XXX	16 Bit Capture Mode
1 11		10	XXX	16 Bit PPG Mode (one-shot mode)
1 11		11	XXX	16 Bit PPG Mode (repeat mode)

11.7.2 16-Bit Timer/Counter Mode

The 16-bit timer/counter mode is selected by control register as shown in Figure 11.22.

The 16-bit timer have counter and data register. The counter register is increased by internal or timer 1 A match clock input. Timer 2 can use the input clock with one of 1, 2, 4, 8, 32, 128, 512 and T1 A Match prescaler division rates (T2CK[2:0]). When the values of T2CNTH/T2CNTL and T2ADRH/T2ADRL are identical in timer 2, a match signal is generated and the interrupt of Timer 2 occurs. The T2CNTH/T2CNTL values are automatically cleared by match signal. It can be also cleared by software (T2CC).

Figure 11.22 16-Bit Timer/Counter Mode for Timer 2

Figure 11.23 16-Bit Timer/Counter 2 Example

The timer 2 capture mode is set by T2MS[1:0] as '01'. The clock source can use the internal clock. Basically, it has the same function as the 16-bit timer/counter mode and the interrupt occurs when T2CNTH/T2CNTL is equal to T2ADRH/T2ADRL. T2CNTH/T2CNTL values are automatically cleared by match signal and it can be also cleared by software (T2CC).

The capture result is loaded into T2BDRH/T2BDRL. In the timer 2 capture mode, timer 2 output(T2O) waveform is not available.

According to EIPOL1 registers setting, the external interrupt EINT12 function is chosen. Of course, the EINT12 pin must be set to an input port.

Figure 11.25 Input Capture Mode Operation for Timer 2

Figure 11.26 Express Timer Overflow in Capture Mode

11.7.4 16-Bit PPG Mode

The timer 2 has a PPG (Programmable Pulse Generation) function. In PPG mode, the T2O/PWM2O pin outputs up to 16-bit resolution PWM output. This pin should be configured as a PWM output by set P1FSRL[3:2] to '11'. The period of the PWM output is determined by the T2ADRH/T2ADRL. And the duty of the PWM output is determined by the T2BDRH/T2BDRL.

One-shot Mode (T2MS = 10b) and "Start High" (T2POL = 0b).

Figure 11.28 16-Bit PPG Mode Timing chart for Timer 2

The diagram illustrates the internal architecture of the T2 timer module. Key components and their interconnections include:

- 16-bit A Data Register (T2ADRH/T2ADRL):** Provides a Reload value to the 16-bit Counter and Buffer Register A.
- Buffer Register A:** Receives the Reload value and outputs the A Match signal to the 16-bit Counter and the T2IFR.
- 16-bit Counter (T2CNTH/T2CNTL):** Receives the Reload value and outputs the B Match signal to the 16-bit Counter and the Pulse Generator. It also outputs the T2EN signal to the MUX.
- 16-bit B Data Register (T2BDRH/T2BDRL):** Provides a Reload value to the 16-bit Counter and Buffer Register B.
- Buffer Register B:** Receives the Reload value and outputs the B Match signal to the 16-bit Counter and the Pulse Generator.
- Pulse Generator:** Receives the B Match signal and outputs the T2MS[1:0] signal to the MUX and the FLAG12 (EIFLAG1.3).
- MUX (Multiplexer):** Selects between the T2EN signal and the T2MS[1:0] signal to output the T2CNTR signal to the 16-bit Counter.
- Interrupt Logic:** The T2IFR and FLAG12 (EIFLAG1.3) are used to generate interrupt signals (INT_ACK and To interrupt block).

11.8 Timer 3, 4

11.8.1 Overview

Timer 3 and timer 4 can be used either two 8-bit timer/counter or one 16-bit timer/counter with combine them. Each 8-bit timer/event counter module has multiplexer, comparator, 8-bit timer data register, 8-bit counter register, control register and capture data register (T3CNT, T3DR, T3CAPR, T3CR, T4CNT, T4DR, T4CAPR, T4CR). For PWM, it has PWM register (T4PPRL, T4PPRH, T4ADRL, T4ADRH, T4BDRL, T4BDRH, T4CDRL, T4CDRH, T4DLYA, T4DLYB, T4DLYC).

It has five operating modes:

- 8-bit timer/counter mode
- 8-bit capture mode
- 16-bit timer/counter mode
- 16-bit capture mode
- 10-bit PWM mode

The timer/counter 3 and 4 can be clocked by an internal or an external clock source (EC3). The clock source is selected by clock selection logic which is controlled by the clock selection bits (T3CK[2:0], T4CK[3:0]). Also the timer/counter 4 can use more clock sources than timer/counter 3.

- TIMER 3 clock source: $f_x/2$, 4, 8, 32, 128, 512, 2048 and EC3
- TIMER 4 clock source: $f_x/1$, 2, 4, 8, 16, 32, 64, 128, 256, 512, 1024, 2048, 4096, 8192, 16384 and T3 clock

In the capture mode, by EINT0/EINT1, the data is captured into input capture data register (T3CAPR, T4CAPR). In 8-bit timer/counter 3/4 mode, whenever counter value is equal to T3DR/T4DR, T3O/T4O port toggles. Also In 16-bit timer/counter 3 mode,

The timer 3 outputs the comparison result between counter and data register through T3O port. The PWM wave form to PWMAA, PWMAB, PWMBA, PWMBB, PWMCA, PWMCB Port (6-channel) in the PWM mode.

Table 11-11 Timer 3, 4 Operating Modes

16BIT	T3MS	T4MS	PWM4E	T3CK[2:0]	T4CK[3:0]	Timer 3	Timer 4
0	0	0	0	XXX	XXXX	8 Bit Timer/Counter Mode	8 Bit Timer/Counter Mode

1	1	1	0	XXX	XXXX	16 Bit Capture Mode	
0	X	X	1	XXX	XXXX	10 Bit PWM Mode	

11.8.2 8-Bit Timer/Counter 3, 4 Mode

The 8-bit timer/counter mode is selected by control register as shown in Figure 11.30.

The two 8-bit timers have each counter and data register. The counter register is increased by internal or external clock input. Timer 3 can use the input clock with one of 2, 4, 8, 32, 128, 512, 2048 and EC3 prescaler division rates (T3CK[2:0]). Timer 4 can use the input clock with one of 1, 2, 4, 8, 16, 32, 64, 128, 256, 512, 1024, 2048, 4096, 8192, 16384 and timer 3 clock prescaler division rates (T4CK[3:0]). When the value of T3CNT, T4CNT and T3DR, T4DR are respectively identical in Timer 3, 4, the interrupt Timer 3, 4 occurs.

The external clock (EC3) counts up the timer at the rising edge. If the EC3 is selected as a clock source by T3CK[2:0], EC3 port should be set to the input port by P00IO bit. Timer 4 can't use the external EC3 clock.

NOTE: Do not set to "1111b" in the T4CK[3:0], when two 8-bit timer 3/4 modes.

Figure 11.30 8-Bit Timer/Counter Mode for Timer 3, 4

11.8.3 16-Bit Timer/Counter 3 Mode

The 16-bit timer/counter mode is selected by control register as shown in Figure 11.31.

The 16-bit timer have counter and data register. The counter register is increased by internal or external clock input. Timer 3 can use the input clock with one of 2, 4, 8, 32, 128, 512 and 2048 prescaler division rates (T3CK[2:0]).

A 16-bit timer/counter register T3CNT, T4CNT are incremented from 0000H to FFFFH until it matches T3DR, T4DR and then cleared to 0000H. The match signal output generates the Timer 3 Interrupt (No timer 4 interrupt). The clock source is selected from T3CK[2:0] and 16BIT bit must be set to '1'. Timer 3 is LSB 8-bit, the timer 4 is MSB 8-bit.

The external clock (EC3) counts up the timer at the rising edge. If the EC3 is selected as a clock source by T3CK[2:0], EC3 port should be set to the input port by P00IO bit.

NOTE) The T4CR.7 bit (16BIT) should be set to '1' and the T4CK[3:0] should be set to "1111b".

Figure 11.31 16-Bit Timer/Counter Mode for Timer 3

11.8.4 8-Bit Timer 3, 4 Capture Mode

The 8-bit Capture 3 and 4 mode is selected by control register as shown in Figure 11.32.

The timer 3, 4 capture mode is set by T3MS, T4MS as '1'. The clock source can use the internal/external clock. Basically, it has the same function as the 8-bit timer/counter mode and the interrupt occurs when T3CNT, T4CNT is equal to T3DR, T4DR. The T3CNT, T4CNT value is automatically cleared by match signal.

This timer interrupt in capture mode is very useful when the pulse width of captured signal is wider than the maximum period of timer.

The capture result is loaded into T3CAPR, T4CAPR. In the timer 3, 4 capture mode, timer 3, 4 output (T3O, T4O) waveform is not available.

According to the EIPOL0L register setting, the external interrupt EINT0 and EINT1 function is chose. Of course, the EINT0 and EINT1 pins must be set to an input port.

The T3CAPR and T3DR are in the same address. In the capture mode, reading operation reads T3CAPR, not T3DR and writing operation will update T3DR. The T4CAPR has the same function.

NOTE: Do not set to "1111b" in the T4CK[3:0], when two 8-bit timer 3/4 modes.

Figure 11.32 8-Bit Capture Mode for Timer 3, 4

11.8.5 16-Bit Timer 3 Capture Mode

The 16-bit Capture mode is selected by control register as shown in Figure 11.33.

The 16-bit capture mode is the same operation as 8-bit capture mode, except that the timer register uses 16 bits. The 16-bit timer 3 capture mode is set by T3MS, T4MS as '1'. The clock source is selected from T3CK[2:0] and 16BIT bit must be set to '1'. Timer 3 is LSB 8-bit, the timer 4 is MSB 8-bit.

NOTE) The T4CR.7 bit (16BIT) should be set to '1' and the T4CK[3:0] should be set to "1111b".

Figure 11.33 16-Bit Capture Mode for Timer 3

11.8.6 10-Bit Timer 4 PWM Mode

The timer 4 has a high speed PWM (Pulse Width Modulation) function. In PWM mode, the 6-channel pins output up to 10-bit resolution PWM output. This pin should be configured as a PWM output by set PWM4E to '1'. When the value of 2bit +T4CNT and T4PPRH/L are identical in timer 4, a period match signal is generated and the interrupt of timer 4 occurs. In 10-bit PWM mode, A, B, C, bottom(underflow) match signal are generated when the 10-bit counter value are identical to the value of T4xADRH/L. The period of the PWM output is determined by the T4PPRH/L (PWM period register), T4xDRH/L (each channel PWM duty register).

PWM Period = [T4PPRH/T4PPRL] X Source Clock

PWM Duty(A-ch) = [T4ADRH/T4ADRL] X Source Clock

Table 11-12 PWM Frequency vs. Resolution at 8 MHz

Resolution	Frequency		
	T4CK[3:0]=0001 (250ns)	T4CK[3:0]=0010 (500ns)	T4CK[3:0]=0100 (2us)
10 Bit	3.9KHz	1.95KHz	0.49KHz
9 Bit	7.8KHz	3.9KHz	0.98KHz
8 Bit	15.6KHz	7.8KHz	1.95KHz
7 Bit	31.2KHz	15.6KHz	3.91KHz

The POLxA bit of T4PCR3 register decides the polarity of duty cycle. If the duty value is set same to the period value, the PWM output is determined by the bit POLxA (1: High, 0: Low). And if the duty value is set to "00H", the PWM output is determined by the bit POLxA (1: Low, 0: High).

Table 11-13 PWM Channel Polarity

PHLT:PxxOE	POLx	A	POLBO	POLxB	PWM4xA Pin Output	PWM4xB Pin Output

Figure 11.35 10-Bit PWM Mode (Force All-ch)

Figure 11.36 Example of PWM at 4 MHz

Figure 11.37 Example of Changing the Period in Absolute Duty Cycle at 4 MHz

Update period & duty register value at once

The period and duty of PWM comes to move from temporary registers to T4PPRH/L (PWM Period Register) and T4ADRH/L/T4BDRH/L/T4CDRH/L (PWM Duty Register) when always period match occurs. If you want that the period and duty is immediately changed, the UPDT bit in the T4PCR1 register must set to '1'. It should be noted that it needs the 3 cycle of timer clock for data transfer in the internal clock synchronization circuit. So the update data is written before 3 cycle of timer clock to get the right output waveform.

Phase correction & Frequency correction

On operating PWM, it is possible that it is changed the phase and the frequency by using BMOD bit (back-to-back mode) in T4PCR1 register. (Figure 1.38, Figure 11.39, Figure 11.40 referred)

In the back-to-back mode, the counter of PWM repeats up/down count. In fact, the effective duty and period becomes twofold of the register set values. (Figure 1.38, Figure 11.39 referred)

Figure 11.38 Example of PWM Output Waveform

Figure 11.39 Example of PWM waveform in Back-to-Back mode at 4 MHz

Figure 11.40 Example of Phase Correction and Frequency correction of PWM

External Sync

If using ESYNC bit of T4PCR1 register, it is possible to synchronize the output of PWM from external signal.

If ESYNC bit sets to '1', the external signal moves to PWM module through the BLNK pin. If BLNK signal is low, immediately PWM output becomes a reset value, and internal counter becomes reset. If BLNK signal returns to '1', the counter is started again and PWM output is normally generated. (Figure 11.41 referred)

PWM Halt

If using PHLT bit of T4PCR1 register, it is possible to stop PWM operation by the software. During PHLT bit being '1', PWM output becomes a reset value, and internal counter becomes reset as 0. Without changing PWM setting, temporarily it is able to stop PWM. In case of T4CNT, when stopping counter, PWM output pin remains before states. But if PHLT bit sets to '1', PWM output pin has reset value.

Figure 11.41 Example of PWM External Synchronization with BLNK Input

FORCE Drive ALL Channel with A-ch mode

If FORCA bit sets to '1', it is possible to enable or disable all PWM output pins through PWM outputs which occur from A-ch duty counter. It is noted that the inversion outputs of A, B, C channel have the same A-ch output waveform. According to POLAA/BB/CC, it is able to control the inversion of outputs.

Figure 11.42 Example of Force Drive All Channel with A-ch

FORCE 6-Ch Drive

If FORCA bit sets to '0', it is possible to enable or disable PWM output pin and inversion output pin generated through the duty counter of each channel. The inversion output is the reverse phase of the PWM output. A AA/AB output of the A-channel duty register, a BA/BB output of the B-channel duty register, a CA/CB output of the C-channel duty register are controlled respectively. If the UALL bit is set to '1', it is updated B/C channel duty at the same time, when it is written by a A-channel duty register.

Figure 11.43 Example of Force Drive 6-ch Mode

PWM output Delay

If using the T4DLYA, T4DLYB, T4DLYC register, it can delay PWM output based on the rising edge. At that time, it does not change the falling edge, so the duty is reduced as the time delay. In POLAA/BA/CA setting to '0', the delay is applied to the falling edge. In POLAA/BA/CA setting to '1', the delay is applied to the rising edge. It can produce a pair of Non-overlapping clock. The each channel is able to have 4-bit delay. As it can select the clock up to 1/8 divided clock using NOPS[1:0] the delay of its maximum 128 timer clock cycle is produced.

Figure 11.44 Example of PWM Delay

CMBMSK	Control Timer 4 PWM B-ch Match Interrupt 0 Disble PWM B-ch match interrupt 1 Enable PWM B-ch match interrupt
CMCMSK	Control Timer 4 PWM C-ch Match Interrupt 0 Disble PWM C-ch match interrupt 1 Enable PWM C-ch match interrupt

11.9 Buzzer Driver

11.9.1 Overview

The Buzzer consists of 8 bit counter, buzzer data register (BUZDR), and buzzer control register (BUZCR). The Square Wave (61.035Hz~125.0 kHz @8MHz) is outputted through P13/SEG17/AN10/EC1/BUZO pin. The buzzer data register (BUZDR) controls the buzzer frequency (look at the following expression). In buzzer control register (BUZCR), BUCK[1:0] selects source clock divided by prescaler.

$$f_{\text{BUZ}}(\text{Hz}) = \frac{\text{Oscillator Frequency}}{2 \times \text{Prescaler Ratio} \times (\text{BUZDR} + 1)}$$

Table 11-15 Buzzer Frequency at 8 MHz

BUZDR[7:0]	Buzzer Frequency (kHz)			
	BUZCR[2:1]=00	BUZCR[2:1]=01	BUZCR[2:1]=10	BUZCR[2:1]=11
0000_0000	125kHz	62.5kHz	31.25kHz	15.625kHz
0000_0001	2.5kHz	31.25kHz	15.625kHz	7.812kHz

11.10.3 Data Transmit / Receive Operation

User can use SPI 2 for serial data communication by following step

1. Select SPI 2 operation mode(master/slave, polarity, phase) by control register SPICR.
2. When the SPI 2 is configured as a Master, it selects a Slave by SS2 signal (active low).
When the SPI 2 is configured as a Slave, it is selected by SS2 signal incoming from Master
3. When the user writes a byte to the data register SPIDR, SPI 2 will start an operation.
4. In this time, if the SPI 2 is configured as a Master, serial clock will come out of SCK2 pin. And Master shifts the eight bits into the Slave (transmit), Slave shifts the eight bits into the Master at the same time (receive). If the SPI 2 is configured as a Slave, serial clock will come into SCK2 pin. And Slave shifts the eight bits into the Master (transmit), Master shifts the eight bits into the Slave at the same time (receive).
5. When transmit/receive is done, SPIIFR bit will be set. If the SPI 2 interrupt is enabled, an interrupt is requested. And SPIIFR bit is cleared by hardware when executing the corresponding interrupt. If SPI 2 interrupt is disable, SPIIFR bit is cleared when user read the status register SPISR, and then access (read/write) the data register SPIDR.

11.10.4 SS2 pin function

1. When the SPI 2 is configured as a Slave, the SS2 pin is always input. If LOW signal come into SS2 pin, the SPI 2 logic is active. And if 'HIGH' signal come into SS2 pin, the SPI 2 logic is stop. In this time, SPI 2 logic will be reset, and invalidated any received data.
2. When the SPI 2 is configured as a Master, the user can select the direction of the SS2 pin by port direction register (P17IO). If the SS2 pin is configured as an output, user can use general P17IO output mode. If the SS2 pin is configured as an input, 'HIGH' signal must come into SS2 pin to guarantee Master operation. If 'LOW' signal come into SS2 pin, the SPI 2 logic interprets this as another master selecting the SPI 2 as a slave and starting to send data to it. To avoid bus contention, MSB bit of SPICR will be cleared and the SPI 2 becomes a Slave and then, SPIIFR bit of SPISR will be set, and if the SPI 2 interrupt is enabled, an interrupt is requested.

NOTES)

- When the SS2 pin is configured as an output at Master mode, SS2 pin's output value is defined by user's software (P17IO). Before SPICR setting, the direction of SS2 pin must be defined
- If you don't need to use SS2 pin, clear the SENA bit of SPISR. So, you can use disabled pin by P17IO freely. In this case, SS2 signal is driven by 'HIGH' or 'LOW' internally. In other words, master is 'HIGH', slave is 'LOW'
- When SS2 pin is configured as input, if 'HIGH' signal come into SS2 pin, SS_HIGH flag bit will be set. And you can clear it by writing '0'.

SPICR B5H		R/W	00H	SPI 2 Control Register

11.10.7 SPI 2 Register Description

The SPI 2 register consists of SPI 2 control register (SPICR), SPI 2 status register (SPISR) and SPI 2 data register (SPIDR)

11.10.8 Register Description for SPI 2

SPIDR (SPI 2 Data Register) : B6H

7	6	5	4	3	2	1	0
SPIDR7	SPIDR6	SPIDR5	SPIDR4	SPIDR3	SPIDR2	SPIDR1	SPIDR0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Initial value : 00H

SPIDR [7:0]

SPI 2 Data

When it is written a byte to this data register, the SPI 2 will start an operation.

SPISR (SPI 2 Status Register) : B7H

7	6	5	4	3	2	1	0
SPIIFR	WCOL	SS_HIGH	–	FXCH	SSENA	–	–
RW	R	RW	–	RW	RW	–	–

Initial value : 00H

SPIIFR	When SPI 2 Interrupt occurs, this bit becomes '1'. IF SPI 2 interrupt is enable, this bit is auto cleared by INT_ACK signal. And if SPI 2 Interrupt is disable, this bit is cleared when the status register SPISR is read, and then access (read/write) the data register SPIDR 0 SPI 2 Interrupt no generation 1 SPI 2 Interrupt generation
WCOL	This bit is set if any data are written to the data register SPIDR during transfer. This bit is cleared when the status register SPISR is read, and then access (read/write) the data register SPIDR 0 No collision 1 Collision
SS_HIGH	When the SS2 pin is configured as input, if "HIGH" signal comes into the pin, this flag bit will be set. 0 Cleared when '0' is written 1 No effect when '1' is written
FXCH	SPI 2 port function exchange control bit. 0 No effect 1 Exchange MOSI2 and MISO2 function
SSENA	This bit controls the SS2 pin operation 0 Disable 1 Enable (The P17 should be a normal input)

SPICR (SPI 2 Control Register) : B5H

7	6	5	4	3	2	1	0
SPIEN	FLSB	MS	CPOL	CPHA	DSCR	SCR1	SCR0
RW	RW	RW	RW	RW	RW	RW	RW

Initial value : 00H

SPIEN	This bit controls the SPI 2 operation 0 Disable SPI 2 operation 1 Enable SPI 2 operation						
FLSB	This bit selects the data transmission sequence 0 MSB first 1 LSB first						
MS	This bit selects whether Master or Slave mode 0 Slave mode 1 Master mode						
CPOL CPHA	This two bits control the serial clock (SCK2) mode. Clock polarity(CPOL) bit determine SCK2's value at idle mode. Clock phase (CPHA) bit determine if data are sampled on the leading or trailing edge of SCK2. CPOL CPHA Leading edge Trailing edge 0 0 Sample (Rising) Setup (Falling) 0 1 Setup (Rising) Sample (Falling) 1 0 Sample (Falling) Setup (Rising) 1 1 Setup (Falling) Sample (Rising)						
DSCR SCR[2:0]	These three bits select the SCK2 rate of the device configured as a master. When DSCR bit is written one, SCK2 will be doubled in master mode. DSCR SCR1 SCR0 SCK2 frequency 0 0 0 fx/4 0 0 1 fx/16 0 1 0 fx/64 0 1 1 fx/128 1 0 0 fx/2 1 0 1 fx/8 1 1 0 fx/32 1 1 1 fx/64						

11.11 12-Bit A/D Converter

11.11.1 Overview

The analog-to-digital converter (A/D) allows conversion of an analog input signal to corresponding 12-bit digital value. The A/D module has eight analog inputs. The output of the multiplexer is the input into the converter which generates the result through successive approximation. The A/D module has four registers which are the A/D converter control high register (ADCCRH), A/D converter control low register (ADCCRL), A/D converter data high register (ADCDRH), and A/D converter data low register (ADCDDL). The channels to be converted are selected by setting ADSEL[3:0]. To execute A/D conversion, TRIG[2:0] bits should be set to 'xxx'. The register ADCDRH and ADCDDL contains the results of the A/D conversion. When the conversion is completed, the result is loaded into the ADCDRH and ADCDDL, the A/D conversion status bit AFLAG is set to '1', and the A/D interrupt is set. During A/D conversion, AFLAG bit is read as '0'.

11.11.2 Conversion Timing

The A/D conversion process requires 4 steps (4 clock edges) to convert each bit and 10 clocks to set up A/D conversion. Therefore, total of 58 clocks are required to complete a 12-bit conversion: When fxx/8 is selected for conversion clock with a 12MHz fxx clock frequency, one clock cycle is 0.66 μ s. Each bit conversion requires 4 clocks, the conversion rate is calculated as follows:

$$4 \text{ clocks/bit} \times 12 \text{ bits} + \text{set-up time} = 58 \text{ clocks,}$$

$$58 \text{ clock} \times 0.66 \mu\text{s} = 38.28 \mu\text{s at } 1.5 \text{ MHz (12 MHz/8)}$$

NOTE) The A/D converter needs at least 20 μ s for conversion time. So you must set the conversion time more than 20 μ s.

11.12 USI0 (UART + SPI + I2C)

11.12.1 Overview

The USI0 consists of USI0 control register1/2/3/4, USI0 status register 1/2, USI0 baud-rate generation register, USI0 data register, USI0 SDA hold time register, USI0 SCL high period register, USI0 SCL low period register, and USI0 slave address register (USI0CR1, USI0CR2, USI0CR3, USI0CR4, USI0ST1, USI0ST2, USI0BD, USI0DR, USI0SDHR, USI0SCHR, USI0SCLR, USI0SAR).

The operation mode is selected by the operation mode of USI0 selection bits (USI0MS[1:0]).

It has four operating modes:

- Asynchronous mode (UART)
- Synchronous mode
- SPI mode
- I2C mode

11.12.2 USI0 UART Mode

The universal synchronous and asynchronous serial receiver and transmitter (UART) is a highly flexible serial communication device. The main features are listed below.

- Full Duplex Operation (Independent Serial Receive and Transmit Registers)
- Asynchronous or Synchronous Operation
- Baud Rate Generator
- Supports Serial Frames with 5,6,7,8, or 9 Data Bits and 1 or 2 Stop Bits
- Odd or Even Parity Generation and Parity Check Supported by Hardware
- Data OverRun Detection
- Framing Error Detection
- Three Separate Interrupts on TX Complete, TX Data Register Empty and RX Complete
- Double Speed Asynchronous communication mode

USI0 has three main parts of clock generator, Transmitter and receiver. The clock generation logic consists of synchronization logic for external clock input used by synchronous or SPI slave operation, and the baud rate generator for asynchronous or master (synchronous or SPI) operation.

The Transmitter consists of a single write buffer, a serial shift register, parity generator and control logic for handling different serial frame formats. The write buffer allows continuous transfer of data without any delay between frames. The receiver is the most complex part of the UART module due to its clock and data recovery units. The recovery unit is used for asynchronous data reception. In addition to the recovery unit, the receiver includes a parity checker, a shift register, a two-level receive FIFO (USI0DR) and control logic. The receiver supports the same frame formats as the transmitter and can detect frame error, data overrun and parity errors.

11.12.3 USI0 UART Block Diagram

Figure 11.57 USI0 UART Block Diagram

The diagram illustrates the SCK0 clock divider circuit. It starts with the **USI0BD** register, which feeds into a **Prescaling Up-Counter**. The output of the counter is $f_{SCLK} (USI0BD+1)$, which is then divided by 8 and then by 2. The resulting signal is fed into a multiplexer (MUX) along with **DBLS0**. The output of this MUX is **txclk**. Another multiplexer (MUX) takes **MASTER0** and **USI0MS[1:0]** as inputs. The output of this MUX is fed into a third multiplexer (MUX) along with **rxclk**. The output of this final MUX is **rxclk**. The **SCLK** signal is fed into a **Sync Register**, which then feeds into an **Edge Detector**. The output of the Edge Detector is fed into a multiplexer (MUX) along with **CPOL0**. The output of this MUX is fed into a fourth multiplexer (MUX) along with **SCK0**. The output of this final MUX is **SCK0**.

The clock generation logic generates the base clock for the transmitter and receiver. The USI0 supports four modes of clock operation and those are normal asynchronous, double speed asynchronous, master synchronous and slave synchronous mode. The clock generation scheme for master SPI and slave SPI mode is the same as master synchronous and slave synchronous operation mode. The USI0MS[1:0] bits in USI0CR1 register selects asynchronous or synchronous operation. Asynchronous double speed mode is controlled by the DBLS0 bit in the USI0CR2 register. The MASTER0 bit in USI0CR3 register controls whether the clock source is internal (master mode, output pin) or external (slave mode, input pin). The SCK0 pin is active only when the USI0 operates in synchronous or SPI mode.

Table 11-19 Equations for Calculating USI0 Baud Rate Register Setting

Operating Mode	Equation for Calculating Baud Rate
Asynchronous Normal Mode (DBLS0=0)	$\text{Baud Rate} = \frac{f_x}{16(USI0BD + 1)}$
Asynchronous Double Speed Mode (DBLS0=1)	$\text{Baud Rate} = \frac{f_x}{8(USI0BD + 1)}$
Synchronous or SPI Master Mode	$\text{Baud Rate} = \frac{f_x}{2(USI0BD + 1)}$

11.12.5 USI0 External Clock (SCK0)

External clocking is used in the synchronous mode of operation.

External clock input from the SCK0 pin is sampled by a synchronization logic to remove meta-stability. The output from the synchronization logic must be passed through an edge detector before it is used by the transmitter and receiver. This process introduces two CPU clock period delay. The maximum frequency of the external SCK0 pin is limited up-to 1MHz.

11.12.6 USI0 Synchronous mode operation

When synchronous or SPI mode is used, the SCK0 pin will be used as either clock input (slave) or clock output (master). Data sampling and transmitter is issued on the different edge of SCK0 clock each other. For example, if data input on RXD0 (MISO0 in SPI mode) pin is sampled on the rising edge of SCK0 clock, data output on TXD0 (MOSI0 in SPI mode) pin is altered on the falling edge.

The CPOL0 bit in USI0CR1 register selects which SCK0 clock edge is used for data sampling and which is used for data change. As shown in the figure below, when CPOL0 is zero, the data will be changed at rising SCK0 edge and sampled at falling SCK0 edge.

Figure 11.59 Synchronous Mode SCK0 Timing (USI0)

11.12.7 USI0 UART Data format

A serial frame is defined to be one character of data bits with synchronization bits (start and stop bits), and optionally a parity bit for error detection.

The UART supports all 30 combinations of the following as valid frame formats.

- 1 start bit
- 5, 6, 7, 8 or 9 data bits
- no, even or odd parity bit
- 1 or 2 stop bits

A frame starts with the start bit followed by the least significant data bit (LSB). Then the next data bits, up to nine, are succeeding, ending with the most significant bit (MSB). If parity function is enabled, the parity bit is inserted between the last data bit and the stop bit. A high-to-low transition on data pin is considered as start bit. When a complete frame is transmitted, it can be directly followed by a new frame, or the communication line can be set to an idle state. The idle means high state of data pin. The following figure shows the possible combinations of the frame formats. Bits inside brackets are optional.

Figure 11.60 Frame Format (USI0)

1 data frame consists of the following bits

- Idle No communication on communication line (TXD0/RXD0)
- St Start bit (Low)
- Dn Data bits (0~8)
- Parity bit ----- Even parity, Odd parity, No parity
- Stop bit(s) ----- 1 bit or 2 bits

The frame format used by the UART is set by the USI0S[2:0], USI0PM[1:0] bits in USI0CR1 register and USI0SB bit in USI0CR3 register. The Transmitter and Receiver use the same setting.

11.12.8 USI0 UART Parity bit

The parity bit is calculated by doing an exclusive-OR of all the data bits. If odd parity is used, the result of the exclusive-O is inverted. The parity bit is located between the MSB and first stop bit of a serial frame.

$$P_{\text{even}} = D_{n-1} \wedge \dots \wedge D_3 \wedge D_2 \wedge D_1 \wedge D_0 \wedge 0$$

$$P_{\text{odd}} = D_{n-1} \wedge \dots \wedge D_3 \wedge D_2 \wedge D_1 \wedge D_0 \wedge 1$$

P_{even} : Parity bit using even parity

P_{odd} : Parity bit using odd parity

D_n : Data bit n of the character

11.12.9 USI0 UART Transmitter

The UART transmitter is enabled by setting the TXE0 bit in USI0CR2 register. When the Transmitter is enabled, the TXD0 pin should be set to TXD0 function for the serial output pin of UART by the P4FSR[3:2]. The baud-rate, operation mode and frame format must be setup once before doing any transmission. In synchronous operation mode, the SCK0 pin is used as transmission clock, so it should be selected to do SCK0 function by P4FSR[5:4].

11.12.9.1 USI0 UART Sending Tx data

A data transmission is initiated by loading the transmit buffer (USI0DR register I/O location) with the data to be transmitted. The data written in transmit buffer is moved to the shift register when the shift register is ready to send a new frame. The shift register is loaded with the new data if it is in idle state or immediately after the last stop bit of the previous frame is transmitted. When the shift register is loaded with new data, it will transfer one complete frame according to the settings of control registers. If the 9-bit characters are used in asynchronous or synchronous operation mode, the ninth bit must be written to the USI0TX8 bit in USI0CR3 register before it is loaded to the transmit buffer (USI0DR register).

11.12.9.2 USI0 UART Transmitter flag and interrupt

The UART transmitter has 2 flags which indicate its state. One is UART data register empty flag (DRE0) and the other is transmit complete flag (TXC0). Both flags can be interrupt sources.

DRE0 flag indicates whether the transmit buffer is ready to receive new data. This bit is set when the transmit buffer is empty and cleared when the transmit buffer contains data to be transmitted but has not yet been moved into the shift register. And also this flag can be cleared by writing '0' to this bit position. Writing '1' to this bit position is prevented.

When the data register empty interrupt enable (DRIE0) bit in USI0CR2 register is set and the global interrupt is enabled, USI0ST1 status register empty interrupt is generated while DRE0 flag is set.

The transmit complete (TXC0) flag bit is set when the entire frame in the transmit shift register has been shifted out and there is no more data in the transmit buffer. The TXC0 flag is automatically cleared when the transmit complete interrupt service routine is executed, or it can be cleared by writing '0' to TXC0 bit in USI0ST1 register.

When the transmit complete interrupt enable (TXCIE0) bit in USI0CR2 register is set and the global interrupt is enabled, UART transmit complete interrupt is generated while TXC0 flag is set.

11.12.9.3 USI0 UART Parity Generator

The parity generator calculates the parity bit for the serial frame data to be sent. When parity bit is enabled (USI0PM1=1), the transmitter control logic inserts the parity bit between the MSB and the first stop bit of the frame to be sent.

11.12.9.4 USI0 UART Disabling Transmitter

Disabling the transmitter by clearing the TXE0 bit will not become effective until ongoing transmission is completed. When the Transmitter is disabled, the TXD0 pin can be used as a normal general purpose I/O (GPIO).

11.12.10 USI0 UART Receiver

The UART receiver is enabled by setting the RXE0 bit in the USI0CR2 register. When the receiver is enabled, the RXD0 pin should be set to RXD0 function for the serial input pin of UART by P4FSR[1:0]. The baud-rate, mode of operation and frame format must be set before serial reception. In synchronous or SPI operation mode the SCK0 pin is used as transfer clock, so it should be selected to do SCK0 function by P4FSR[5:4]. In SPI operation mode the SS0 input pin in slave mode or can be configured as SS0 output pin in master mode. This can be done by setting USI0SSEN bit in USI0CR3 register.

11.12.10.1 USI0 UART Receiving Rx data

When UART is in synchronous or asynchronous operation mode, the receiver starts data reception when it detects a valid start bit (LOW) on RXD0 pin. Each bit after start bit is sampled at pre-defined baud-rate (asynchronous) or sampling edge of SCK0 (synchronous), and shifted into the receive shift register until the first stop bit of a frame is received. Even if there's 2nd stop bit in the frame, the 2nd stop bit is ignored by the receiver. That is, receiving the first stop bit means that a complete serial frame is present in the receiver shift register and contents of the shift register are to be moved into the receive buffer. The receive buffer is read by reading the USI0DR register.

If 9-bit characters are used (USI0S[2:0] = "111"), the ninth bit is stored in the USI0RX8 bit position in the USI0CR3 register. The 9th bit must be read from the USI0RX8 bit before reading the low 8 bits from the USI0DR register. Likewise, the error flags FE0, DOR0, PE0 must be read before reading the data from USI0DR register. It's because the error flags are stored in the same FIFO position of the receive buffer.

11.12.10.2 USI0 UART Receiver Flag and Interrupt

The UART receiver has one flag that indicates the receiver state.

The receive complete (RXC0) flag indicates whether there are unread data in the receive buffer. This flag is set when there are unread data in the receive buffer and cleared when the receive buffer is empty. If the receiver is disabled (RXE0=0), the receiver buffer is flushed and the RXC0 flag is cleared.

When the receive complete interrupt enable (RXCIE0) bit in the USI0CR2 register is set and global interrupt is enabled, the UART receiver complete interrupt is generated while RXC0 flag is set.

The UART receiver has three error flags which are frame error (FE0), data overrun (DOR0) and parity error (PE0). These error flags can be read from the USI0ST1 register. As received data are stored in the 2-level receive buffer, these error flags are also stored in the same position of receive buffer. So, before reading received data from USI0DR register, read the USI0ST1 register first which contains error flags.

The frame error (FE0) flag indicates the state of the first stop bit. The FE0 flag is '0' when the stop bit was correctly detected as "1", and the FE0 flag is "1" when the stop bit was incorrect, i.e. detected as "0". This flag can be used for detecting out-of-sync conditions between data frames.

The data overrun (DOR0) flag indicates data loss due to a receive buffer full condition. DOR0 occurs when the receive buffer is full, and another new data is present in the receive shift register which are to be stored into the receive buffer. After the DOR0 flag is set, all the incoming data are lost. To prevent data loss or clear this flag, read the receive buffer.

The parity error (PE0) flag indicates that the frame in the receive buffer had a parity error when received. If parity check function is not enabled (USI0PM1=0), the PE bit is always read "0".

11.12.10.3 USI0 UART Parity Checker

If parity bit is enabled (USI0PM1=1), the Parity Checker calculates the parity of the data bits in incoming frame and compares the result with the parity bit from the received serial frame.

11.12.10.4 USI0 UART Disabling Receiver

In contrast to transmitter, disabling the Receiver by clearing RXE0 bit makes the Receiver inactive immediately. When the receiver is disabled, the receiver flushes the receive buffer, the remaining data in the buffer is all reset, and the RXD0 pin can be used as a normal general purpose I/O (GPIO).

11.12.10.5 USI0 Asynchronous Data Reception

To receive asynchronous data frame, the UART includes a clock and data recovery unit. The clock recovery logic is used for synchronizing the internally generated baud-rate clock to the incoming asynchronous serial frame on the RXD0 pin.

The data recovery logic samples and low pass filters the incoming bits, and this removes the noise of RXD0 pin.

The next figure illustrates the sampling process of the start bit of an incoming frame. The sampling rate is 16 times of the baud-rate in normal mode and 8 times the aud-rate for double speed mode (DBLS0=1). The horizontal arrows show the synchronization variation due to the asynchronous sampling process. Note that larger time variation is shown when using the double speed mode.

Figure 11.61 Asynchronous Start Bit Sampling (USI0)

When the receiver is enabled (RXE0=1), the clock recovery logic tries to find a high-to-low transition on the RXD0 line, the start bit condition. After detecting high to low transition on RXD0 line, the clock recovery logic uses samples 8, 9 and 10 for normal mode to decide if a valid start bit is received. If more than 2 samples have logical low level, it is considered that a valid start bit is detected and the internally generated clock is synchronized to the incoming data frame. And the data recovery can begin. The synchronization process is repeated for each start bit.

As described above, when the receiver clock is synchronized to the start bit, the data recovery can begin. Data recovery process is almost similar to the clock recovery process. The data recovery logic samples 16 times for each incoming bits for normal mode and 8 times for double speed mode, and uses sample 8, 9 and 10 to decide data value. If more than 2 samples have low levels, the received bit is considered to a logic '0' and if more than 2 samples have high levels, the received bit is considered to a logic '1'. The data recovery process is then repeated until a complete frame is received including the first stop bit. The decided bit value is stored in the receive shift register in order. Note that the Receiver only uses the first stop bit of a frame. Internally, after receiving the first stop bit, the Receiver is in idle state and waiting to find start bit.

Figure 11.62 Asynchronous Sampling of Data and Parity Bit (USI0)

The process for detecting stop bit is like clock and data recovery process. That is, if 2 or more samples of 3 center values have high level, correct stop bit is detected, else a frame error (FE0) flag is set. After deciding whether the first stop bit is valid or not, the Receiver goes to idle state and monitors the RXD0 line to check a valid high to low transition is detected (start bit detection).

Figure 11.63 Stop Bit Sampling and Next Start Bit Sampling (USI0)

11.12.11 USI0 SPI Mode

The USI0 can be set to operate in industrial standard SPI compliant mode. The SPI mode has the following features.

- Full Duplex, Three-wire synchronous data transfer
- Master and Slave Operation
- Supports all four SPI0 modes of operation (mode 0, 1, 2, and 3)
- Selectable LSB first or MSB first data transfer
- Double buffered transmit and receive
- Programmable transmit bit rate

When SPI mode is enabled (USI0MS[1:0]="11"), the slave select (SS0) pin becomes active LOW input in slave mode operation, or can be output in master mode operation if USI0SSEN bit is set to '0'.

Note that during SPI mode of operation, the pin RXD0 is renamed as MISO0 and TXD0 is renamed as MOSI0 for compatibility to other SPI devices.

11.12.12 USI0 SPI Clock Formats and Timing

To accommodate a wide variety of synchronous serial peripherals from different manufacturers, the USI0 has a clock polarity bit (CPOL0) and a clock phase control bit (CPHA0) to select one of four clock formats for data transfers. CPOL0 selectively insert an inverter in series with the clock. CPHA0 chooses between two different clock phase relationships between the clock and data. Note that CPHA0 and CPOL0 bits in USI0CR1 register have different meanings according to the USI0MS[1:0] bits which decides the operating mode of USI0.

Table below shows four combinations of CPOL0 and CPHA0 for SPI mode 0, 1, 2, and 3.

Table 11-20 CPOL0 Functionality

SPI Mode	CPOL0	CPHA0	Leading Edge	Trailing Edge
0 0		0 Sam	ple (Rising)	Setup (Falling)
1 0		1 Set	up (Rising)	Sample (Falling)
2 1		0 Sam	ple (Falling)	Setup (Rising)
3 1		1 Set	up (Falling)	Sample (Rising)

Figure 11.64 USI0 SPI Clock Formats when CPHA0=0

When CPHA0=0, the slave begins to drive its MISO0 output with the first data bit value when SS0 goes to active low. The first SCK0 edge causes both the master and the slave to sample the data bit value on their MISO0 and MOSI0 inputs, respectively. At the second SCK0 edge, the USI0 shifts the second data bit value out to the MOSI0 and MISO0 outputs of the master and slave, respectively. Unlike the case of CPHA0=1, when CPHA0=0, the slave's SS0 input must go to its inactive high level between transfers. This is because the slave can prepare the first data bit when it detects falling edge of SS0 input.

Figure 11.65 USI0 SPI Clock Formats when CPHA0=1

When CPHA0=1, the slave begins to drive its MISO0 output when SS0 goes active low, but the data is not defined until the first SCK0 edge. The first SCK0 edge shifts the first bit of data from the shifter onto the MOSI0 output of the master and the MISO0 output of the slave. The next SCK0 edge causes both the master and slave to sample the data bit value on their MISO0 and MOSI0 inputs, respectively. At the third SCK0 edge, the USI0 shifts the second data bit value out to the MOSI0 and MISO0 output of the master and slave respectively. When CPHA0=1, the slave's SS0 input is not required to go to its inactive high level between transfers.

Because the SPI logic reuses the USI0 resources, SPI mode of operation is similar to that of synchronous or asynchronous operation. An SPI transfer is initiated by checking for the USI0 Data Register Empty flag (DRE0=1) and then writing a byte of data to the USI0DR Register. In master mode of operation, even if transmission is not enabled (TXE0=0), writing data to the USI0DR register is necessary because the clock SCK0 is generated from transmitter block.

11.12.13 USI0 SPI Block Diagram

Figure 11.66 USI0 SPI Block Diagram

11.12.14 USI0 I2C Mode

The USI0 can be set to operate in industrial standard serial communication protocols mode. The I2C mode uses 2 bus lines serial data line (SDA0) and serial clock line (SCL0) to exchange data. Because both SDA0 and SCL0 lines are open-drain output, each line needs pull-up resistor. The features are as shown below.

- Compatible with I2C bus standard
- Multi-master operation
- Up to 400kHz data transfer read speed
- 7 bit address
- Both master and slave operation
- Bus busy detection

11.12.15 USI0 I2C Bit Transfer

The data on the SDA0 line must be stable during HIGH period of the clock, SCL0. The HIGH or LOW state of the data line can only change when the clock signal on the SCL0 line is LOW. The exceptions are START(S), repeated START(Sr) and STOP(P) condition where data line changes when clock line is high.

Figure 11.67 Bit Transfer on the I2C-Bus (USI0)

11.12.16 USI0 I2C Start / Repeated Start / Stop

One master can issue a START (S) condition to notice other devices connected to the SCL0, SDA0 lines that it will use the bus. A STOP (P) condition is generated by the master to release the bus lines so that other devices can use it.

A high to low transition on the SDA0 line while SCL0 is high defines a START (S) condition.

A low to high transition on the SDA0 line while SCL0 is high defines a STOP (P) condition.

START and STOP conditions are always generated by the master. The bus is considered to be busy after START condition. The bus is considered to be free again after STOP condition, ie, the bus is busy between START and STOP condition. If a repeated START condition (Sr) is generated instead of STOP condition, the bus stays busy. So, the START and repeated START conditions are functionally identical.

Figure 11.68 START and STOP Condition (USI0)

11.12.17 USI0 I2C Data Transfer

Every byte put on the SDA0 line must be 8-bits long. The number of bytes that can be transmitted per transfer is unlimited. Each byte has to be followed by an acknowledge bit. Data is transferred with the most significant bit (MSB) first. If a slave can't receive or transmit another complete byte of data until it has performed some other function, it can hold the clock line SCL0 LOW to force the master into a wait state. Data transfer then continues when the slave is ready for another byte of data and releases clock line SCL0.

Figure 11.69 Data Transfer on the I2C-Bus (USI0)

11.12.18 USI0 I2C Acknowledge

The acknowledge related clock pulse is generated by the master. The transmitter releases the SDA0 line (HIGH) during the acknowledge clock pulse. The receiver must pull down the SDA0 line during the acknowledge clock pulse so that it remains stable LOW during the HIGH period of this clock pulse. When a slave is addressed by a master (Address Packet), and if it is unable to receive or transmit because it's performing some real time function, the data line must be left HIGH by the slave. And also, when a slave addressed by a master is unable to receive more data bits, the slave receiver must release the SDA0 line (Data Packet). The master can then generate either a STOP condition to abort the transfer, or a repeated START condition to start a new transfer.

If a master receiver is involved in a transfer, it must signal the end of data to the slave transmitter by not generating an acknowledge on the last byte that was clocked out of the slave. The slave transmitter must release the data line to allow the master to generate a STOP or repeated START condition.

Figure 11.70 Acknowledge on the I2C-Bus (USI0)

11.12.19 USI0 I2C Synchronization / Arbitration

Clock synchronization is performed using the wired-AND connection of I2C interfaces to the SCL0 line. This means that a HIGH to LOW transition on the SCL0 line will cause the devices concerned to start counting off their LOW period and it will hold the SCL0 line in that state until the clock HIGH state is reached. However the LOW to HIGH transition of this clock may not change the state of the SCL0 line if another clock is still within its LOW period. In this way, a synchronized SCL0 clock is generated with its LOW period determined by the device with the longest clock LOW period, and its HIGH period determined by the one with the shortest clock HIGH period.

A master may start a transfer only if the bus is free. Two or more masters may generate a START condition. Arbitration takes place on the SDA0 line, while the SCL0 line is at the HIGH level, in such a way that the master which transmits a HIGH level, while another master is transmitting a LOW level will switch off its DATA output state because the level on the bus doesn't correspond to its own level. Arbitration continues for many bits until a winning master gets the ownership of I2C bus. Its first stage is comparison of the address bits.

Figure 11.71 Clock Synchronization during Arbitration Procedure (USI0)

Figure 11.72 Arbitration Procedure of Two Masters (USI0)

11.12.20 USI0 I2C Operation

The I2C is byte-oriented and interrupt based. Interrupts are issued after all bus events except for a transmission of a START condition. Because the I2C is interrupt based, the application software is free to carry on other operations during a I2C byte transfer.

Note that when a I2C interrupt is generated, IIC0IFR flag in USI0CR4 register is set, it is cleared by writing an any value to USI0ST2. When I2C interrupt occurs, the SCL0 line is hold LOW until writing any value to USI0ST2. When the IIC0IFR flag is set, the USI0ST2 contains a value indicating the current state of the I2C bus. According to the value in USI0ST2, software can decide what to do next.

I2C can operate in 4 modes by configuring master/slave, transmitter/receiver. The operating mode is configured by a winning master. A more detailed explanation follows below.

11.12.20.1 USI0 I2C Master Transmitter

To operate I2C in master transmitter, follow the recommended steps below.

1. Enable I2C by setting USI0MS[1:0] bits in USI0CR1 and USI0EN bit in USI0CR2. This provides main clock to the peripheral.
2. Load SLA0+W into the USI0DR where SLA0 is address of slave device and W is transfer direction from the viewpoint of the master. For master transmitter, W is '0'. Note that USI0DR is used for both address and data.
3. Configure baud rate by writing desired value to both USI0SCLR and USI0SCHR for the Low and High period of SCL0 line.
4. Configure the USI0SDHR to decide when SDA0 changes value from falling edge of SCL0. If SDA0 should change in the middle of SCL0 LOW period, load half the value of USI0SCLR to the USI0SDHR.
5. Set the STARTC0 bit in USI0CR4. This transmits a START condition. And also configure how to handle interrupt and ACK signal. When the STARTC0 bit is set, 8-bit data in USI0DR is transmitted out according to the baud-rate.
6. This is ACK signal processing stage for address packet transmitted by master. When 7-bit address and 1-bit transfer direction is transmitted to target slave device, the master can know whether the slave acknowledged or not in the 9th high period of SCL0. If the master gains bus mastership, I2C generates GCALL interrupt regardless of the reception of ACK from the slave device. When I2C loses bus mastership during arbitration process, the MLOST0 bit in USI0ST2 is set, and I2C waits in idle state or can be operate as an addressed slave. To operate as a slave when the MLOST0 bit in USI0ST2 is set, the ACK0EN bit in USI0CR4 must be set and the received 7-bit address must equal to the USI0SLA[6:0] bits in USI0SAR. In this case I2C operates as a slave transmitter or a slave receiver (go to appropriate section). In this stage, I2C holds the SCL0 LOW. This is because to decide whether I2C continues serial transfer or stops communication. The following steps continue assuming that I2C does not lose mastership during first data transfer.

I2C (Master) can choose one of the following cases regardless of the reception of ACK signal from slave.

- 1) Master receives ACK signal from slave, so continues data transfer because slave can receive more data from master. In this case, load data to transmit to USI0DR.
- 2) Master stops data transfer even if it receives ACK signal from slave. In this case, set the STOPC0 bit in USI0CR4.
- 3) Master transmits repeated START condition with not checking ACK signal. In this case, load SLA0+R/W into the USI0DR and set STARTC0 bit in USI0CR4.

After doing one of the actions above, write any arbitrary to USI0ST2 to release SCL0 line. In case of 1), move to step 7. In case of 2), move to step 9 to handle STOP interrupt. In case of 3), move to step 6 after transmitting the data in USI0DR and if transfer direction bit is '1' go to master receiver section.

7. 1-Byte of data is being transmitted. During data transfer, bus arbitration continues.
8. This is ACK signal processing stage for data packet transmitted by master. I2C holds the SCL0 LOW. When I2C loses bus mastership while transmitting data arbitrating other masters, the MLOST0 bit in USI0ST2 is set. If then, I2C waits in idle state. When the data in USI0DR is transmitted completely, I2C generates TEND0 interrupt.

I2C can choose one of the following cases regardless of the reception of ACK signal from slave.

- 1) Master receives ACK signal from slave, so continues data transfer because slave can receive more data from master. In this case, load data to transmit to USI0DR.
- 2) Master stops data transfer even if it receives ACK signal from slave. In this case, set the STOPC0 bit in USI0CR4.
- 3) Master transmits repeated START condition with not checking ACK signal. In this case, load SLA0+R/W into the USI0DR and set the STARTC0 bit in USI0CR4.

After doing one of the actions above, write any arbitrary to USI0ST2 to release SCL0 line. In case of 1), move to step 7. In case of 2), move to step 9 to handle STOP interrupt. In case of 3), move to step 6 after transmitting the data in USI0DR, and if transfer direction bit is '1' go to master receiver section.

9. This is the final step for master transmitter function of I2C, handling STOP interrupt. The STOP bit indicates that data transfer between master and slave is over. To clear USI0ST2, write any value to USI0ST2. After this, I2C enters idle state.

The next figure depicts above process for master transmitter operation of I2C.

Figure 11.73 Formats and States in the Master Transmitter Mode (USI0)

11.12.20.2 USI0 I2C Master Receiver

To operate I2C in master receiver, follow the recommended steps below.

1. Enable I2C by setting USI0MS[1:0] bits in USI0CR1 and USI0EN bit in USI0CR2. This provides main clock to the peripheral.
2. Load SLA0+R into the USI0DR where SLA is address of slave device and R is transfer direction from the viewpoint of the master. For master receiver, R is '1'. Note that USI0DR is used for both address and data.
3. Configure baud rate by writing desired value to both USI0SCLR and USI0SCHR for the Low and High period of SCL0 line.
4. Configure the USI0SDHR to decide when SDA0 changes value from falling edge of SCL0. If SDA0 should change in the middle of SCL0 LOW period, load half the value of USI0SCLR to the USI0SDHR.
5. Set the STARTC0 bit in USI0CR4. This transmits a START condition. And also configure how to handle interrupt and ACK signal. When the STARTC0 bit is set, 8-bit data in USI0DR is transmitted out according to the baud-rate.
6. This is ACK signal processing stage for address packet transmitted by master. When 7-bit address and 1-bit transfer direction is transmitted to target slave device, the master can know whether the slave acknowledged or not in the 9th high period of SCL0. If the master gains bus mastership, I2C generates GCALL interrupt regardless of the reception of ACK from the slave device. When I2C loses bus mastership during arbitration process, the MLOST0 bit in USI0ST2 is set, and I2C waits in idle state or can be operate as an addressed slave. To operate as a slave when the MLOST0 bit in USI0ST2 is set, the ACK0EN bit in USI0CR4 must be set and the received 7-bit address must equal to the USI0SLA[6:0] bits in USI0SAR. In this case I2C operates as a slave transmitter or a slave receiver (go to appropriate section). In this stage, I2C holds the SCL0 LOW. This is because to decide whether I2C continues serial transfer or stops communication. The following steps continue assuming that I2C does not lose mastership during first data transfer.

I2C (Master) can choose one of the following cases according to the reception of ACK signal from slave.

- 1) Master receives ACK signal from slave, so continues data transfer because slave can prepare and transmit more data to master. Configure ACK0EN bit in USI0CR4 to decide whether I2C ACKnowledges the next data to be received or not.
- 2) Master stops data transfer because it receives no ACK signal from slave. In this case, set the STOPC0 bit in USI0CR4.
- 3) Master transmits repeated START condition due to no ACK signal from slave. In this case, load SLA0+R/W into the USI0DR and set STARTC0 bit in USI0CR4.

After doing one of the actions above, write arbitrary value to USI0ST2 to release SCL0 line. In case of 1), move to step 7. In case of 2), move to step 9 to handle STOP interrupt. In case of 3), move to step 6 after transmitting the data in USI0DR and if transfer direction bit is '0' go to master transmitter section.

7. 1-Byte of data is being received.
8. This is ACK signal processing stage for data packet transmitted by slave. I2C holds the SCL0 LOW. When 1-Byte of data is received completely, I2C generates TEND0 interrupt.

I2C0 can choose one of the following cases according to the RXACK0 flag in USI0ST2.

- 1) Master continues receiving data from slave. To do this, set ACK0EN bit in USI0CR4 to ACKnowledge the next data to be received.
- 2) Master wants to terminate data transfer when it receives next data by not generating ACK signal. This can be done by clearing ACK0EN bit in USI0CR4.
- 3) Because no ACK signal is detected, master terminates data transfer. In this case, set the STOPC0 bit in USI0CR4.
- 4) No ACK signal is detected, and master transmits repeated START condition. In this case, load SLA0+R/W into the USI0DR and set the STARTC0 bit in USI0CR4.

After doing one of the actions above, write arbitrary value to USI0ST2 to release SCL0 line. In case of 1) and 2), move to step 7. In case of 3), move to step 9 to handle STOP interrupt. In case of 4), move to step 6 after transmitting the data in USI0DR, and if transfer direction bit is '0' go to master transmitter section.

- The processes described above for master receiver operation of I2C can be depicted as the following figure.

11.12.20.3 USI0 I2C Slave Transmitter

To operate I2C in slave transmitter, follow the recommended steps below.

1. If the main operating clock (SCLK) of the system is slower than that of SCL0, load value 0x00 into USI0SDHR to make SDA0 change within one system clock period from the falling edge of SCL0. Note that the hold time of SDA0 is calculated by SDAH x period of SCLK where SDAH is multiple of number of SCLK coming from USI0SDHR. When the hold time of SDA0 is longer than the period of SCLK, I2C (slave) cannot transmit serial data properly.
2. Enable I2C by setting USI0MS[1:0] bits in USI0CR1, IIC0IE bit in USI0CR4 and USI0EN bit in USI0CR2. This provides main clock to the peripheral.
3. When a START condition is detected, I2C receives one byte of data and compares it with USI0SLA[6:0] bits in USI0SAR. If the GCALL0 bit in USI0SAR is enabled, I2C compares the received data with value 0x00, the general call address.
4. If the received address does not equal to USI0SLA[6:0] bits in USI0SAR, I2C enters idle state ie, waits for another START condition. Else if the address equals to USI0SLA[6:0] bits and the ACK0EN bit is enabled, I2C generates SSEL0 interrupt and the SCL0 line is held LOW. Note that even if the address equals to USI0SLA[6:0] bits, when the ACK0EN bit is disabled, I2C enters idle state. When SSEL0 interrupt occurs, load transmit data to USI0DR and write arbitrary value to USI0ST2 to release SCL0 line.
5. 1-Byte of data is being transmitted.
6. In this step, I2C generates TEND0 interrupt and holds the SCL0 line LOW regardless of the reception of ACK signal from master. Slave can select one of the following cases.
 - 1) No ACK signal is detected and I2C waits STOP or repeated START condition.
 - 2) ACK signal from master is detected. Load data to transmit into USI0DR.

After doing one of the actions above, write arbitrary value to USI0ST2 to release SCL0 line. In case of 1) move to step 7 to terminate communication. In case of 2) move to step 5. In either case, a repeated START condition can be detected. For that case, move step 4.

7. This is the final step for slave transmitter function of I2C, handling STOP interrupt. The STOPC0 bit indicates that data transfer between master and slave is over. To clear USI0ST2, write any value to USI0ST2. After this, I2C enters idle state.

The next figure shows flow chart for handling slave transmitter function of I2C.

Figure 11.75 Formats and States in the Slave Transmitter Mode (USI0)

11.12.20.4 USI0 I2C Slave Receiver

To operate I2C in slave receiver, follow the recommended steps below.

1. If the main operating clock (SCLK) of the system is slower than that of SCL0, load value 0x00 into USI0SDHR to make SDA0 change within one system clock period from the falling edge of SCL0. Note that the hold time of SDA0 is calculated by SDAH x period of SCLK where SDAH is multiple of number of SCLK coming from USI0SDHR. When the hold time of SDA0 is longer than the period of SCLK, I2C (slave) cannot transmit serial data properly.
2. Enable I2C by setting USI0MS[1:0] bits in USI0CR1, IIC0IE bit in USI0CR4 and USI0EN bit in USI0CR2. This provides main clock to the peripheral.
3. When a START condition is detected, I2C receives one byte of data and compares it with USI0SLA[6:0] bits in USI0SAR. If the GCALL0 bit in USI0SAR is enabled, I2C0 compares the received data with value 0x00, the general call address.
4. If the received address does not equal to SLA0bits in USI0SAR, I2C enters idle state ie, waits for another START condition. Else if the address equals to SLA0 bits and the ACK0EN bit is enabled, I2C generates SSEL0 interrupt and the SCL0 line is held LOW. Note that even if the address equals to SLA0 bits, when the ACK0EN bit is disabled, I2C enters idle state. When SSEL0 interrupt occurs and I2C is ready to receive data, write arbitrary value to USI0ST2 to release SCL0 line.
5. 1-Byte of data is being received.
6. In this step, I2C generates TEND0 interrupt and holds the SCL0 line LOW regardless of the reception of ACK signal from master. Slave can select one of the following cases.
 - 1) No ACK signal is detected (ACK0EN=0) and I2C waits STOP or repeated START condition.
 - 2) ACK signal is detected (ACK0EN=1) and I2C can continue to receive data from master.

After doing one of the actions above, write arbitrary value to USI0ST2 to release SCL0 line. In case of 1) move to step 7 to terminate communication. In case of 2) move to step 5. In either case, a repeated START condition can be detected. For that case, move step 4.

7. This is the final step for slave receiver function of I2C, handling STOP interrupt. The STOPC0 bit indicates that data transfer between master and slave is over. To clear USI0ST2, write any value to USI0ST2. After this, I2C enters idle state.

The process can be depicted as following figure when I2C operates in slave receiver mode.

Figure 11.76 Formats and States in the Slave Receiver Mode (USI0)

11.12.21 USI0 I2C Block Diagram

NOTE) When the USI0 block is an I2C mode and the corresponding port is an sub-function for SCL0/SDA0 pin, the SCL0/SDA0 pins are automatically set to the N-channel open-drain outputs and the input latch is read in the case of reading the pins. The corresponding pull-up resistor is determined by the control register.

Figure 11.77 USI0 I2C Block Diagram

11.12.22 Register Map

Table 11-21 USI0 Register Map

Name	Address	Dir	Default	Description
USI0BD	E3H	R/W	FFH	USI0 Baud Rate Generation Register

11.12.23 USI0 Register Description

USI0 module consists of USI0 baud rate generation register (USI0BD), USI0 data register (USI0DR), USI0 SDA hold time register (USI0SDHR), USI0 SCL high period register (USI0SCHR), USI0 SCL low period Register (USI0SCLR), USI0 slave address register (USI0SAR), USI0 control register 1/2/3/4 (USI0CR1/2/3/4), USI0 status register 1/2 (USI0ST1/2).

11.12.24 Register Description for USI0

USI0BD (USI0 Baud- Rate Generation Register: For UART and SPI mode) : E3H

7	6	5	4	3	2	1	0
USI0BD7	USI0BD6	USI0BD5	USI0BD4	USI0BD3	USI0BD2	USI0BD1	USI0BD0
RW	RW	RW	RW	RW	RW	RW	RW

Initial value : FFH

USI0BD[7:0]

The value in this register is used to generate internal baud rate in asynchronous mode or to generate SCK0 clock in SPI mode. To prevent malfunction, do not write '0' in asynchronous mode and do not write '0' or '1' in SPI mode.

NOTE) In common with USI0SAR register, USI0BD register is used for slave address register when the USI0 I2C mode.

USI0DR (USI0 Data Register: For UART, SPI, and I2C mode) : E5H

7	6	5	4	3	2	1	0
USI0DR7	USI0DR6	USI0DR5	USI0DR4	USI0DR3	USI0DR2	USI0DR1	USI0DR0
RW	RW	RW	RW	RW	RW	RW	RW

Initial value : 00H

USI0DR[7:0]

The USI0 transmit buffer and receive buffer share the same I/O address with this DATA register. The transmit data buffer is the destination for data written to the USI0DR register. Reading the USI0DR register returns the contents of the receive buffer.

Write to this register only when the DRE0 flag is set. In SPI master mode, the SCK clock is generated when data are written to this register.

USI0SDHR (USI0 SDA Hold Time Register: For I2C mode) : E4H

7	6	5	4	3	2	1	0
USI0SDHR7	USI0SDHR6	USI0SDHR5	USI0SDHR4	USI0SDHR3	USI0SDHR2	USI0SDHR1	USI0SDHR0
RW	RW	RW	RW	RW	RW	RW	RW

Initial value : 00H

USI0SDHR[7:0]

The register is used to control SDA0 output timing from the falling edge of SCL in I2C mode.

NOTE) That SDA0 is changed after $t_{SCLK} \times (USI0SDHR+2)$, in master SDA0 change in the middle of SCL0.

In slave mode, configure this register regarding the frequency of SCL0 from master.

The SDA0 is changed after $t_{sclk} \times (USI0SDHR+2)$ in master mode. So, to insure operation in slave mode, the value

$t_{SCLK} \times (USI0SDHR + 2)$ must be smaller than the period of SCL.

USI0SCHR (USI0 SCL High Period Register: For I2C mode) : E7H

7	6	5	4	3	2	1	0
USI0SCHR7	USI0SCHR6	USI0SCHR5	USI0SCHR4	USI0SCHR3	USI0SCHR2	USI0SCHR1	USI0SCHR0
RW	RW	RW	RW	RW	RW	RW	RW

Initial value : 00H

USI0SCHR[7:0]

This register defines the high period of SCL0 when it operates in I2C master mode.

The base clock is SCLK, the system clock, and the period is calculated by the formula: $t_{SCLK} \times (4 \times USI0SCHR + 2)$ where

t_{SCLK} is the period of SCLK.

So, the operating frequency of I2C master mode is calculated by the following equation.

$$f_{I2C} = \frac{1}{t_{SCLK} \times (4 \times (USI0SCLR + USI0SCHR + 4))}$$

USI0SCLR (USI0 SCL Low Period Register: For I2C mode) : E6H

7	6	5	4	3	2	1	0
USI0SCLR7	USI0SCLR6	USI0SCLR5	USI0SCLR4	USI0SCLR3	USI0SCLR2	USI0SCLR1	USI0SCLR0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Initial value : 00H

USI0SCLR[7:0] This register defines the high period of SCL0 when it operates in I2C master mode.
The base clock is S CLK, the system clock, and the period is calculated by the formula: $t_{SCLK} \times (4 \times USI0SCLR + 2)$ where t_{SCLK} is the period of SCLK.

USI0SAR (USI0 Slave Address Register: For I2C mode) : DDH

7	6	5	4	3	2	1	0
USI0SLA6	USI0SLA5	USI0SLA4	USI0SLA3	USI0SLA2	USI0SLA1	USI0SLA0	USI0GCE
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Initial value : 00H

USI0SLA[6:0] These bits configure the slave address of I2C when it operates in I2C slave mode.

UPM[1:0] This bit decides whether I2C allows general call address or not in I2C slave mode.

- 0 Ignore general call address
- 1 Allow general call address

USI0CR1 (USI0 Control Register 1: For UART, SPI, and I2C mode) : D9H

7	6	5	4	3	2	1	0
USI0MS1	USI0MS0	USI0PM1	USI0PM0	USI0S2	USI0S1 ORD0	USI0S0 CPHA0	CPOL0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Initial value : 00H

USI0MS[1:0]	Selects operation mode of USI0			
	USI0MS1	USI0MS0	Operation mode	
	0 0		Asynchronous Mode (UART)	
	0 1		Synchronous Mode	
	1 0		I2C mode	
	1 1		SPI mode	
USI0PM[1:0]	Selects parity generation and check methods (only UART mode)			
	USI0PM1	USI0PM0	Parity	
	0 0		No Parity	
	0 1		Reserved	
	1 0		Even Parity	
	1 1		Odd Parity	
USI0S[2:0]	When in asynchronous or synchronous mode of operation, selects the length of data bits in frame			
	USI0S2	USI0S1	USI0S0	Data Length
	0 0		0	5 bit
	0 0		1	6 bit
	0 1		0	7 bit
	0 1		1	8 bit
	1 0		0	Reserved
	1 0		1	Reserved
	1 1		0	Reserved
	1 1		1	9 bit
ORD0	This bit in the same bit position with USI0S1. The MSB of the data byte is transmitted first when set to '1' and the LSB when set to '0' (only SPI mode)			
	0	LS	B-first	
	1	MSB-	first	
CPOL0	This bit determines the clock polarity of ACK in synchronous or SPI mode.			
	0	TXD change@Rising Edge, RXD change@Falling Edge		
	1	TXD change@Falling Edge, RXD change@Rising Edge		
CPHA0	This bit is in the same bit position with USI0S0. This bit determines if data are sampled on the leading or trailing edge of SCK0 (only SPI mode).			
	CPOL0	CPHA0	Leading edge	Trailing edge
	0	0	Sample (Rising)	Setup (Falling)
	0	1	Setup (Rising)	Sample (Falling)
	1	0	Sample (Falling)	Setup (Rising)
	1	1	Setup (Falling)	Sample (Rising)

USI0CR2 (USI0 Control Register 2: For UART, SPI, and I2C mode) : DAH

7	6	5	4	3	2	1	0
DRIE0	TXCIE0	RXCIE0	WAKEIE0	TXE0	RXE0	USI0EN	DBLS0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Initial value : 00H

DRIE0	Interrupt enable bit for data register empty (only UART and SPI mode). 0 Interrupt from DRE0 is inhibited (use polling) 1 When DRE0 is set, request an interrupt
TXCIE0	Interrupt enable bit for transmit complete (only UART and SPI mode). 0 Interrupt from TXC0 is inhibited (use polling) 1 When TXC0 is set, request an interrupt
RXCIE0	Interrupt enable bit for receive complete (only UART and SPI mode). 0 Interrupt from RXC0 is inhibited (use polling) 1 When RXC0 is set, request an interrupt
WAKEIE0	Interrupt enable bit for asynchronous wake in STOP mode. When device is in stop mode, if RXD0 goes to low level an interrupt can be requested to wake-up system. (only UART mode). At that time the DRIE0 bit and USI0ST1 register value should be set to '0b' and "00H", respectively. 0 Interrupt from Wake is inhibited 1 When WAKE0 is set, request an interrupt
TXE0	Enables the transmitter unit (only UART and SPI mode). 0 Transmitter is disabled 1 Transmitter is enabled
RXE0	Enables the receiver unit (only UART and SPI mode). 0 Receiver is disabled 1 Receiver is enabled
USI0EN	Activate USI0 function block by supplying. 0 USI0 is disabled 1 USI0 is enabled
DBLS0	This bit selects receiver sampling rate (only UART). 0 Normal asynchronous operation 1 Double Speed asynchronous operation

USI0CR3 (USI0 Control Register 3: For UART, SPI, and I2C mode) : DBH

7	6	5	4	3	2	1	0
MASTER0	LOOPS0	DISSCK0	USI0SEN	FXCH0	USI0SB	USI0TX8	USI0RX8
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R

Initial value : 00H

MASTER0	Selects master or slave in SPI and synchronous mode operation and controls the direction of SCK0 pin 0 Slave mode operation (External clock for SCK0). 1 Master mode operation (Internal clock for SCK0).
LOOPS0	Controls the loop back mode of USI0 for test mode (only UART and SPI mode) 0 Normal operation 1 Loop Back mode
DISSCK0	In synchronous mode of operation, selects the waveform of SCK0 output 0 ACK is free-running while UART is enabled in synchronous master mode 1 ACK is active while any frame is on transferring
USI0SEN	This bit controls the SS0 pin operation (only SPI mode) 0 Disable 1 Enable (The SS0 pin should be a normal input)
FXCH0	SPI port function exchange control bit (only SPI mode) 0 No effect 1 Exchange MOSI0 and MISO0 function
USI0SB	Selects the length of stop bit in asynchronous or synchronous mode of operation. 0 1 Stop Bit 1 2 Stop Bit
USI0TX8	The ninth bit of data frame in asynchronous or synchronous mode of operation. Write this bit first before loading the USI0DR register 0 MSB (9 th bit) to be transmitted is '0' 1 MSB (9 th bit) to be transmitted is '1'
USI0RX8	The ninth bit of data frame in asynchronous or synchronous mode of operation. Read this bit first before reading the receive buffer (only UART mode). 0 MSB (9 th bit) received is '0' 1 MSB (9 th bit) received is '1'

USI0CR4 (USI0 Control Register 4: For I2C mode) : DCH

7	6	5	4	3	2	1	0
IIC0IFR	—	TXDLYENB0	IIC0IE	ACK0EN	IMASTER0	STOPC0	STARTC0
R	—	RW	RW	RW	R	RW	RW

Initial value : 00H

IIC0IFR	This is an interrupt flag bit for I2C mode. When an interrupt occurs, this bit becomes '1'. This bit is cleared when write any values in th USI0ST2. 0 I2C interrupt no generation 1 I2C interrupt generation
TXDLYENB0	USI0SDHR register control bit 0 Enable USI0SDHR register 1 Disable USI0SDHR register
IIC0IE	Interrupt Enable bit for I2C mode 0 Interrupt from I2C is inhibited (use polling) 1 Enable interrupt for I2C
ACK0EN	Controls ACK signal Generation at ninth SCL0 period. 0 No ACK signal is generated (SDA0 =1) 1 ACK signal is generated (SDA0 =0) NOTES) ACK signal is output (SDA =0) for the following 3 cases. 1. When received address packet equals to USI0SLA bits in USI0SAR. 2. When received address packet equals to value 0x00 with GC ALL0 enabled. 3. When I2C operates as a receiver (master or slave)
IMASTER0	Represent operating mode of I2C 0 I2C is in slave mode 1 I2C is in master mode
STOPC0	When I2C is master, STOP condition generation 0 No effect 1 STOP condition is to be generated
STARTC0	When I2C is master, START condition generation 0 No effect 1 START or repeated START condition is to be generated

USI0ST1 (USI0 Status Register 1: For UART and SPI mode) : E1H

7	6	5	4	3	2	1	0
DRE0	TXC0	RXC0	WAKE0	USI0RST	DOR0	FE0	PE0
R/W	R/W	R	R/W	R/W	R	R/W	R/W

Initial value : 80H

DRE0	The DR E0 flag indicates if the transmit buffer (USI0DR) is ready to receive new data. If DRE0 is '1', the buffer is empty and ready to be written. This flag can generate a DRE0 interrupt.
0	Transmit buffer is not empty.
1	Transmit buffer is empty.
TXC0	This flag is set when the entire frame in the transmit shift register has been shifted out and there is no new data currently present in the transmit buffer. This flag is automatically cleared when the interrupt service routine of a TXC0 interrupt is executed. This flag can generate a TXC0 interrupt. This bit is automatically cleared.
0	Transmission is ongoing.
1	Transmit buffer is empty and the data in transmit shift register are shifted out completely.
RXC0	This flag is set when there are unread data in the receive buffer and cleared when all the data in the receive buffer are read. The RXC0 flag can be used to generate a RXC0 interrupt.
0	There is no data unread in the receive buffer
1	There are more than 1 data in the receive buffer
WAKE0	This flag is set when the RXD0 pin is detected low while the CPU is in STOP mode. This flag can be used to generate a WAKE0 interrupt. This bit is set only when in asynchronous mode of operation. This bit should be cleared by program software. (only UART mode)
0	No WAKE interrupt is generated.
1	WAKE interrupt is generated
USI0RST	This is an internal reset and only has effect on USI0. Writing '1' to this bit initializes the internal logic of USI0 and this bit is automatically cleared to '0'.
0	No operation
1	Reset USI0
DOR0	This bit is set if a Data OverRun occurs. While this bit is set, the incoming data frame is ignored. This flag is valid until the receive buffer is read.
0	No Data OverRun
1	Data OverRun detected
FE0	This bit is set if the first stop bit of next character in the receive buffer is detected as '0'. This bit is valid until the receive buffer is read. (only UART mode)
0	No Frame Error
1	Frame Error detected
PE0	This bit is set if the next character in the receive buffer has a Parity Error to be received while Parity Checking is enabled. This bit is valid until the receive buffer is read. (only UART mode)
0	No Parity Error
1	Parity Error detected

USI0ST2 (USI0 Status Register 2: For I2C mode) : E2H

7	6	5	4	3	2	1	0
GCALL0	TEND0	STOPD0	SSEL0	MLOST0	BUSY0	TMODE0	RXACK0
R	RW	RW	RW	RW	RW	RW	RW

Initial value : 00H

GCALL0^(NOTE) This bit has different meaning depending on whether I2C is master or slave. When I2C is a master, this bit represents whether it received AACK (address ACK) from slave.

0 No AACK is received (Master mode)

1 AACK is received (Master mode)

When I2C is a slave, this bit is used to indicate general call.

0 General call address is not detected (Slave mode)

1 General call address is detected (Slave mode)

TEND0^(NOTE) This bit is set when 1-byte of data is transferred completely

0 1 byte of data is not completely transferred

1 1 byte of data is completely transferred

STOPD0^(NOTE) This bit is set when a STOP condition is detected.

0 No STOP condition is detected

1 STOP condition is detected

SSEL0^(NOTE) This bit is set when I2C is addressed by other master.

0 I2C is not selected as a slave

1 I2C is addressed by other master and acts as a slave

MLOST0^(NOTE) This bit represents the result of bus arbitration in master mode.

0 I2C maintains bus mastership

1 I2C maintains bus mastership during arbitration process

BUSY0 This bit reflects bus status.

0 I2C bus is idle, so a master can issue a START condition

1 I2C bus is busy

TMODE0 This bit is used to indicate whether I2C is transmitter or receiver.

0 I2C is a receiver

1 I2C is a transmitter

RXACK0 This bit shows the state of ACK signal

0 No ACK is received

1 ACK is received at ninth SCL period

NOTE) These bits can be source of interrupt.

When an I2C interrupt occurs except for STOP mode, the SCL0 line is held LOW. To release SCL0, write arbitrary value to USI0ST2. When USI0ST2 is written, the TEND0, STOPD0, SSEL0, MLOST0, and RXACK0 bits are cleared.

11.13 USI1 (UART + SPI + I2C)

11.13.1 Overview

The USI1 consists of USI1 control register1/2/3/4, USI1 status register 1/2, USI1 baud-rate generation register, USI1 data register, USI1 SDA hold time register, USI1 SCL high period register, USI1 SCL low period register, and USI1 slave address register (USI1CR1, USI1CR2, USI1CR3, USI1CR4, USI1ST1, USI1ST2, USI1BD, USI1DR, USI1SDHR, USI1SCHR, USI1SCLR, USI1SAR).

The operation mode is selected by the operation mode of USI1 selection bits (USI1MS[1:0]).

It has four operating modes:

- Asynchronous mode (UART)
- Synchronous mode
- SPI mode
- I2C mode

11.13.2 USI1 UART Mode

The universal synchronous and asynchronous serial receiver and transmitter (UART) is a highly flexible serial communication device. The main features are listed below.

- Full Duplex Operation (Independent Serial Receive and Transmit Registers)
- Asynchronous or Synchronous Operation
- Baud Rate Generator
- Supports Serial Frames with 5,6,7,8, or 9 Data Bits and 1 or 2 Stop Bits
- Odd or Even Parity Generation and Parity Check Supported by Hardware
- Data OverRun Detection
- Framing Error Detection
- Three Separate Interrupts on TX Complete, TX Data Register Empty and RX Complete
- Double Speed Asynchronous communication mode

USI1 has three main parts of clock generator, Transmitter and receiver. The clock generation logic consists of synchronization logic for external clock input used by synchronous or SPI slave operation, and the baud rate generator for asynchronous or master (synchronous or SPI) operation.

The Transmitter consists of a single write buffer, a serial shift register, parity generator and control logic for handling different serial frame formats. The write buffer allows continuous transfer of data without any delay between frames. The receiver is the most complex part of the UART module due to its clock and data recovery units. The recovery unit is used for asynchronous data reception. In addition to the recovery unit, the receiver includes a parity checker, a shift register, a two-level receive FIFO (USI1DR) and control logic. The receiver supports the same frame formats as the transmitter and can detect frame error, data overrun and parity errors.

11.13.3 USI1 UART Block Diagram

Figure 11.78 USI1 UART Block Diagram

11.13.4 USI1 Clock Generation

Figure 11.79 Clock Generation Block Diagram (USI1)

The clock generation logic generates the base clock for the transmitter and receiver. The USI1 supports four modes of clock operation and those are normal asynchronous, double speed asynchronous, master synchronous and slave synchronous mode. The clock generation scheme for master SPI and slave SPI mode is the same as master synchronous and slave synchronous operation mode. The USI1MS[1:0] bits in USI1CR1 register selects asynchronous or synchronous operation. Asynchronous double speed mode is controlled by the DBLS1 bit in the USI1CR2 register. The MASTER1 bit in USI1CR3 register controls whether the clock source is internal (master mode, output pin) or external (slave mode, input pin). The SCK1 pin is active only when the USI1 operates in synchronous or SPI mode.

Following table shows the equations for calculating the baud rate (in bps).

Table 11-22 Equations for Calculating USI1 Baud Rate Register Setting

Operating Mode	Equation for Calculating Baud Rate
Asynchronous Normal Mode (DBLS1=0)	$\text{Baud Rate} = \frac{f_x}{16(\text{USI1BD} + 1)}$
Asynchronous Double Speed Mode (DBLS1=1)	$\text{Baud Rate} = \frac{f_x}{8(\text{USI1BD} + 1)}$
Synchronous or SPI Master Mode	$\text{Baud Rate} = \frac{f_x}{2(\text{USI1BD} + 1)}$

11.13.5 USI1 External Clock (SCK1)

External clocking is used in the synchronous mode of operation.

External clock input from the SCK1 pin is sampled by a synchronization logic to remove meta-stability. The output from the synchronization logic must be passed through an edge detector before it is used by the transmitter and receiver. This process introduces two CPU clock period delay. The maximum frequency of the external SCK1 pin is limited up-to 1MHz.

11.13.6 USI1 Synchronous mode operation

When synchronous or SPI mode is used, the SCK1 pin will be used as either clock input (slave) or clock output (master). Data sampling and transmitter is issued on the different edge of SCK1 clock each other. For example, if data input on RXD1 (MISO1 in SPI mode) pin is sampled on the rising edge of SCK1 clock, data output on TXD1 (MOSI1 in SPI mode) pin is altered on the falling edge.

The CPOL1 bit in USI1CR1 register selects which SCK1 clock edge is used for data sampling and which is used for data change. As shown in the figure below, when CPOL1 is zero, the data will be changed at rising SCK1 edge and sampled at falling SCK1 edge.

Figure 11.80 Synchronous Mode SCK1 Timing (USI1)

11.13.7 USI1 UART Data format

A serial frame is defined to be one character of data bits with synchronization bits (start and stop bits), and optionally a parity bit for error detection.

The UART supports all 30 combinations of the following as valid frame formats.

- 1 start bit
- 5, 6, 7, 8 or 9 data bits
- no, even or odd parity bit
- 1 or 2 stop bits

A frame starts with the start bit followed by the least significant data bit (LSB). Then the next data bits, up to nine, are succeeding, ending with the most significant bit (MSB). If parity function is enabled, the parity bit is inserted between the last data bit and the stop bit. A high-to-low transition on data pin is considered as start bit. When a complete frame is transmitted, it can be directly followed by a new frame, or the communication line can be set to an idle state. The idle means high state of data pin. The following figure shows the possible combinations of the frame formats. Bits inside brackets are optional.

Figure 11.81 Frame Format (USI1)

1 data frame consists of the following bits

- Idle No communication on communication line (TXD0/RXD0)
- St Start bit (Low)
- Dn Data bits (0~8)
- Parity bit ----- Even parity, Odd parity, No parity
- Stop bit(s) ----- 1 bit or 2 bits

The frame format used by the UART is set by the USI1S[2:0], USI1PM[1:0] bits in USI1CR1 register and USI1SB bit in USI1CR3 register. The Transmitter and Receiver use the same setting.

11.13.8 USI1 UART Parity bit

The parity bit is calculated by doing an exclusive-OR of all the data bits. If odd parity is used, the result of the exclusive-O is inverted. The parity bit is located between the MSB and first stop bit of a serial frame.

$$P_{\text{even}} = D_{n-1} \wedge \dots \wedge D_3 \wedge D_2 \wedge D_1 \wedge D_0 \wedge 0$$

$$P_{\text{odd}} = D_{n-1} \wedge \dots \wedge D_3 \wedge D_2 \wedge D_1 \wedge D_0 \wedge 1$$

P_{even} : Parity bit using even parity

P_{odd} : Parity bit using odd parity

D_n : Data bit n of the character

11.13.9 USI1 UART Transmitter

The UART transmitter is enabled by setting the TXE1 bit in USI1CR2 register. When the Transmitter is enabled, the TXD1 pin should be set to TXD1 function for the serial output pin of UART by the P2FSR[1:0]. The baud-rate, operation mode and frame format must be setup once before doing any transmission. In synchronous operation mode, the SCK1 pin is used as transmission clock, so it should be selected to do SCK1 function by P2FSR[3:2].

11.13.9.1 USI1 UART Sending Tx data

A data transmission is initiated by loading the transmit buffer (USI1DR register I/O location) with the data to be transmitted. The data written in transmit buffer is moved to the shift register when the shift register is ready to send a new frame. The shift register is loaded with the new data if it is in idle state or immediately after the last stop bit of the previous frame is transmitted. When the shift register is loaded with new data, it will transfer one complete frame according to the settings of control registers. If the 9-bit characters are used in asynchronous or synchronous operation mode, the ninth bit must be written to the USI1TX8 bit in USI1CR3 register before it is loaded to the transmit buffer (USI1DR register).

11.13.9.2 USI1 UART Transmitter flag and interrupt

The UART transmitter has 2 flags which indicate its state. One is UART data register empty flag (DRE1) and the other is transmit complete flag (TXC1). Both flags can be interrupt sources.

DRE1 flag indicates whether the transmit buffer is ready to receive new data. This bit is set when the transmit buffer is empty and cleared when the transmit buffer contains data to be transmitted but has not yet been moved into the shift register. And also this flag can be cleared by writing '0' to this bit position. Writing '1' to this bit position is prevented.

When the data register empty interrupt enable (DRIE1) bit in USI1CR2 register is set and the global interrupt is enabled, USI1ST1 status register empty interrupt is generated while DRE1 flag is set.

The transmit complete (TXC1) flag bit is set when the entire frame in the transmit shift register has been shifted out and there is no more data in the transmit buffer. The TXC1 flag is automatically cleared when the transmit complete interrupt service routine is executed, or it can be cleared by writing '0' to TXC1 bit in USI1ST1 register.

When the transmit complete interrupt enable (TXCIE1) bit in USI1CR2 register is set and the global interrupt is enabled, UART transmit complete interrupt is generated while TXC1 flag is set.

11.13.9.3 USI1 UART Parity Generator

The parity generator calculates the parity bit for the serial frame data to be sent. When parity bit is enabled (USI1PM1=1), the transmitter control logic inserts the parity bit between the MSB and the first stop bit of the frame to be sent.

11.13.9.4 USI1 UART Disabling Transmitter

Disabling the transmitter by clearing the TXE1 bit will not become effective until ongoing transmission is completed. When the Transmitter is disabled, the TXD1 pin can be used as a normal general purpose I/O (GPIO).

11.13.10 USI1 UART Receiver

The UART receiver is enabled by setting the RXE1 bit in the USI1CR2 register. When the receiver is enabled, the RXD1 pin should be set to RXD1 function for the serial input pin of UART by P1FSR[1:0]. The baud-rate, mode of operation and frame format must be set before serial reception. In synchronous or SPI operation mode the SCK1 pin is used as transfer clock, so it should be selected to do SCK1 function by P2FSR[3:2]. In SPI operation mode the SS1 input pin in slave mode or can be configured as SS1 output pin in master mode. This can be done by setting USI1SEN bit in USI1CR3 register.

11.13.10.1 USI1 UART Receiving Rx data

When UART is in synchronous or asynchronous operation mode, the receiver starts data reception when it detects a valid start bit (LOW) on RXD1 pin. Each bit after start bit is sampled at pre-defined baud-rate (asynchronous) or sampling edge of SCK1 (synchronous), and shifted into the receive shift register until the first stop bit of a frame is received. Even if there's 2nd stop bit in the frame, the 2nd stop bit is ignored by the receiver. That is, receiving the first stop bit means that a complete serial frame is present in the receiver shift register and contents of the shift register are to be moved into the receive buffer. The receive buffer is read by reading the USI1DR register.

If 9-bit characters are used (USI1S[2:0] = "111"), the ninth bit is stored in the USI1RX8 bit position in the USI1CR3 register. The 9th bit must be read from the USI1RX8 bit before reading the low 8 bits from the USI1DR register. Likewise, the error flags FE1, DOR1, PE1 must be read before reading the data from USI1DR register. It's because the error flags are stored in the same FIFO position of the receive buffer.

11.13.10.2 USI1 UART Receiver Flag and Interrupt

The UART receiver has one flag that indicates the receiver state.

The receive complete (RXC1) flag indicates whether there are unread data in the receive buffer. This flag is set when there are unread data in the receive buffer and cleared when the receive buffer is empty. If the receiver is disabled (RXE1=1), the receiver buffer is flushed and the RXC1 flag is cleared.

When the receive complete interrupt enable (RXCIE1) bit in the USI1CR2 register is set and global interrupt is enabled, the UART receiver complete interrupt is generated while RXC1 flag is set.

The UART receiver has three error flags which are frame error (FE1), data overrun (DOR1) and parity error (PE1). These error flags can be read from the USI1ST1 register. As received data are stored in the 2-level receive buffer, these error flags are also stored in the same position of receive buffer. So, before reading received data from USI1DR register, read the USI1ST1 register first which contains error flags.

The frame error (FE1) flag indicates the state of the first stop bit. The FE1 flag is '0' when the stop bit was correctly detected as "1", and the FE1 flag is "1" when the stop bit was incorrect, i.e. detected as "0". This flag can be used for detecting out-of-sync conditions between data frames.

The data overrun (DOR1) flag indicates data loss due to a receive buffer full condition. DOR1 occurs when the receive buffer is full, and another new data is present in the receive shift register which are to be stored into the receive buffer. After the DOR1 flag is set, all the incoming data are lost. To prevent data loss or clear this flag, read the receive buffer.

The parity error (PE1) flag indicates that the frame in the receive buffer had a parity error when received. If parity check function is not enabled (USI1PM1=0), the PE bit is always read "0".

11.13.10.3 USI1 UART Parity Checker

If parity bit is enabled (USI1PM1=1), the Parity Checker calculates the parity of the data bits in incoming frame and compares the result with the parity bit from the received serial frame.

11.13.10.4 USI1 UART Disabling Receiver

In contrast to transmitter, disabling the Receiver by clearing RXE1 bit makes the Receiver inactive immediately. When the receiver is disabled, the receiver flushes the receive buffer, the remaining data in the buffer is all reset, and the RXD1 pin can be used as a normal general purpose I/O (GPIO).

11.13.10.5 US11 Asynchronous Data Reception

To receive asynchronous data frame, the UART includes a clock and data recovery unit. The clock recovery logic is used for synchronizing the internally generated baud-rate clock to the incoming asynchronous serial frame on the RXD1 pin.

The data recovery logic samples and low pass filters the incoming bits, and this removes the noise of RXD1 pin.

The next figure illustrates the sampling process of the start bit of an incoming frame. The sampling rate is 16 times of the baud-rate in normal mode and 8 times the baud-rate for double speed mode (DBLS1=1). The horizontal arrows show the synchronization variation due to the asynchronous sampling process. Note that larger time variation is shown when using the double speed mode.

Figure 11.82 Asynchronous Start Bit Sampling (US11)

When the receiver is enabled (RXE1=1), the clock recovery logic tries to find a high-to-low transition on the RXD1 line, the start bit condition. After detecting high to low transition on RXD1 line, the clock recovery logic uses samples 8, 9 and 10 for normal mode to decide if a valid start bit is received. If more than 2 samples have logical low level, it is considered that a valid start bit is detected and the internally generated clock is synchronized to the incoming data frame. And the data recovery can begin. The synchronization process is repeated for each start bit.

As described above, when the receiver clock is synchronized to the start bit, the data recovery can begin. Data recovery process is almost similar to the clock recovery process. The data recovery logic samples 16 times for each incoming bits for normal mode and 8 times for double speed mode, and uses sample 8, 9 and 10 to decide data value. If more than 2 samples have low levels, the received bit is considered to a logic '0' and if more than 2 samples have high levels, the received bit is considered to a logic '1'. The data recovery process is then repeated until a complete frame is received including the first stop bit. The decided bit value is stored in the receive shift register in order. Note that the Receiver only uses the first stop bit of a frame. Internally, after receiving the first stop bit, the Receiver is in idle state and waiting to find start bit.

Figure 11.83 Asynchronous Sampling of Data and Parity Bit (US11)

The process for detecting stop bit is like clock and data recovery process. That is, if 2 or more samples of 3 center values have high level, correct stop bit is detected, else a frame error (FE1) flag is set. After deciding whether the first stop bit is valid or not, the Receiver goes to idle state and monitors the RXD1 line to check a valid high to low transition is detected (start bit detection).

Figure 11.84 Stop Bit Sampling and Next Start Bit Sampling (USI1)

11.13.11 USI1 SPI Mode

The USI1 can be set to operate in industrial standard SPI compliant mode. The SPI mode has the following features.

- Full Duplex, Three-wire synchronous data transfer
- Master and Slave Operation
- Supports all four SPI0 modes of operation (mode 0, 1, 2, and 3)
- Selectable LSB first or MSB first data transfer
- Double buffered transmit and receive
- Programmable transmit bit rate

When SPI mode is enabled (USI1MS[1:0]="11"), the slave select (SS1) pin becomes active LOW input in slave mode operation, or can be output in master mode operation if USI1SSEN bit is set to '0'.

Note that during SPI mode of operation, the pin RXD1 is renamed as MISO1 and TXD1 is renamed as MOSI1 for compatibility to other SPI devices.

11.13.12 USI1 SPI Clock Formats and Timing

To accommodate a wide variety of synchronous serial peripherals from different manufacturers, the USI1 has a clock polarity bit (CPOL1) and a clock phase control bit (CPHA1) to select one of four clock formats for data transfers. CPOL1 selectively insert an inverter in series with the clock. CPHA1 chooses between two different clock phase relationships between the clock and data. Note that CPHA1 and CPOL1 bits in USI1CR1 register have different meanings according to the USI1MS[1:0] bits which decides the operating mode of USI1.

Table below shows four combinations of CPOL1 and CPHA1 for SPI mode 0, 1, 2, and 3.

Table 11-23 CPOL1 Functionality

SPI Mode	CPOL1	CPHA1	Leading Edge	Trailing Edge
0 0		0	Sample (Rising)	Setup (Falling)
1 0		1	Setup (Rising)	Sample (Falling)
2	1	0	Sample (Falling)	Setup (Rising)
3	1	1	Setup (Falling)	Sample (Rising)

Figure 11.85 USI1 SPI Clock Formats when CPHA1=0

When CPHA1=0, the slave begins to drive its MISO1 output with the first data bit value when SS1 goes to active low. The first SCK1 edge causes both the master and the slave to sample the data bit value on their MISO1 and MOSI1 inputs, respectively. At the second SCK1 edge, the USI1 shifts the second data bit value out to the MOSI1 and MISO1 outputs of the master and slave, respectively. Unlike the case of CPHA1=1, when CPHA1=0, the slave's SS1 input must go to its inactive high level between transfers. This is because the slave can prepare the first data bit when it detects falling edge of SS1 input.

Figure 11.86 USI1 SPI Clock Formats when CPHA1=1

When $CPHA1=1$, the slave begins to drive its MISO1 output when SS1 goes active low, but the data is not defined until the first SCK1 edge. The first SCK1 edge shifts the first bit of data from the shifter onto the MOSI1 output of the master and the MISO1 output of the slave. The next SCK1 edge causes both the master and slave to sample the data bit value on their MISO1 and MOSI1 inputs, respectively. At the third SCK1 edge, the USI1 shifts the second data bit value out to the MOSI1 and MISO1 output of the master and slave respectively. When $CPHA1=1$, the slave's SS1 input is not required to go to its inactive high level between transfers.

Because the SPI logic reuses the USI1 resources, SPI mode of operation is similar to that of synchronous or asynchronous operation. An SPI transfer is initiated by checking for the USI1 Data Register Empty flag ($DRE1=1$) and then writing a byte of data to the USI1DR Register. In master mode of operation, even if transmission is not enabled ($TXE1=0$), writing data to the USI1DR register is necessary because the clock SCK1 is generated from transmitter block.

11.13.13 USI1 SPI Block Diagram

Figure 11.87 USI1 SPI Block Diagram

11.13.14 USI1 I2C Mode

The USI1 can be set to operate in industrial standard serial communication protocols mode. The I2C mode uses 2 bus lines serial data line (SDA1) and serial clock line (SCL1) to exchange data. Because both SDA1 and SCL1 lines are open-drain output, each line needs pull-up resistor. The features are as shown below.

- Compatible with I2C bus standard
- Multi-master operation
- Up to 400kHz data transfer read speed
- 7 bit address
- Both master and slave operation
- Bus busy detection

11.13.15 USI1 I2C Bit Transfer

The data on the SDA1 line must be stable during HIGH period of the clock, SCL1. The HIGH or LOW state of the data line can only change when the clock signal on the SCL1 line is LOW. The exceptions are START(S), repeated START(Sr) and STOP(P) condition where data line changes when clock line is high.

Figure 11.88 Bit Transfer on the I2C-Bus (USI1)

One master can issue a START (S) condition to notice other devices connected to the SCL1, SDA1 lines that it will use the bus. A STOP (P) condition is generated by the master to release the bus lines so that other devices can use it.

A low to high transition on the SDA1 line while SCL1 is high defines a STOP (P) condition.

START and STOP conditions are always generated by the master. The bus is considered to be busy after START condition. The bus is considered to be free again after STOP condition, ie, the bus is busy between START and STOP condition. If a repeated START condition (S_r) is generated instead of STOP condition, the bus stays busy. So, the START and repeated START conditions are functionally identical.

Figure 11.89 START and STOP Condition (USI1)

Every byte put on the SDA1 line must be 8-bits long. The number of bytes that can be transmitted per transfer is unlimited. Each byte has to be followed by an acknowledge bit. Data is transferred with the most significant bit (MSB) first. If a slave can't receive or transmit another complete byte of data until it has performed some other function, it can hold the clock line SCL1 LOW to force the master into a wait state. Data transfer then continues when the slave is ready for another byte of data and releases clock line SCL1.

Figure 11.90 Data Transfer on the I2C-Bus (USI1)

11.13.18 USI1 I2C Acknowledge

The acknowledge related clock pulse is generated by the master. The transmitter releases the SDA1 line (HIGH) during the acknowledge clock pulse. The receiver must pull down the SDA1 line during the acknowledge clock pulse so that it remains stable LOW during the HIGH period of this clock pulse. When a slave is addressed by a master (Address Packet), and if it is unable to receive or transmit because it's performing some real time function, the data line must be left HIGH by the slave. And also, when a slave addressed by a master is unable to receive more data bits, the slave receiver must release the SDA1 line (Data Packet). The master can then generate either a STOP condition to abort the transfer, or a repeated START condition to start a new transfer.

If a master receiver is involved in a transfer, it must signal the end of data to the slave transmitter by not generating an acknowledge on the last byte that was clocked out of the slave. The slave transmitter must release the data line to allow the master to generate a STOP or repeated START condition.

Figure 11.91 Acknowledge on the I2C-Bus (USI1)

11.13.19 USI1 I2C Synchronization / Arbitration

Clock synchronization is performed using the wired-AND connection of I2C interfaces to the SCL1 line. This means that a HIGH to LOW transition on the SCL1 line will cause the devices concerned to start counting off their LOW period and it will hold the SCL1 line in that state until the clock HIGH state is reached. However the LOW to HIGH transition of this clock may not change the state of the SCL1 line if another clock is still within its LOW period. In this way, a synchronized SCL1 clock is generated with its LOW period determined by the device with the longest clock LOW period, and its HIGH period determined by the one with the shortest clock HIGH period.

A master may start a transfer only if the bus is free. Two or more masters may generate a START condition. Arbitration takes place on the SDA1 line, while the SCL1 line is at the HIGH level, in such a way that the master which transmits a HIGH level, while another master is transmitting a LOW level will switch off its DATA output state because the level on the bus doesn't correspond to its own level. Arbitration continues for many bits until a winning master gets the ownership of I2C bus. Its first stage is comparison of the address bits.

Figure 11.92 Clock Synchronization during Arbitration Procedure (USI1)

Figure 11.93 Arbitration Procedure of Two Masters (USI1)

11.13.20 USI1 I2C Operation

The I2C is byte-oriented and interrupt based. Interrupts are issued after all bus events except for a transmission of a START condition. Because the I2C is interrupt based, the application software is free to carry on other operations during a I2C byte transfer.

Note that when a I2C interrupt is generated, IIC1IFR flag in USI1CR4 register is set, it is cleared by writing an any value to USI1ST2. When I2C interrupt occurs, the SCL1 line is hold LOW until writing any value to USI1ST2. When the IIC1IFR flag is set, the USI1ST2 contains a value indicating the current state of the I2C bus. According to the value in USI1ST2, software can decide what to do next.

I2C can operate in 4 modes by configuring master/slave, transmitter/receiver. The operating mode is configured by a winning master. A more detailed explanation follows below.

11.13.20.1 USI1 I2C Master Transmitter

To operate I2C in master transmitter, follow the recommended steps below.

10. Enable I2C by setting USI1MS[1:0] bits in USI1CR1 and USI1EN bit in USI1CR2. This provides main clock to the peripheral.
11. Load SLA1+W into the USI1DR where SLA1 is address of slave device and W is transfer direction from the viewpoint of the master. For master transmitter, W is '0'. Note that USI1DR is used for both address and data.
12. Configure baud rate by writing desired value to both USI1SCLR and USI1SCHR for the Low and High period of SCL1 line.
13. Configure the USI0SDHR to decide when SDA1 changes value from falling edge of SCL1. If SDA1 should change in the middle of SCL1 LOW period, load half the value of USI1SCLR to the USI1SDHR.
14. Set the STARTC1 bit in USI1CR4. This transmits a START condition. And also configure how to handle interrupt and ACK signal. When the STARTC1 bit is set, 8-bit data in USI1DR is transmitted out according to the baud-rate.
15. This is ACK signal processing stage for address packet transmitted by master. When 7-bit address and 1-bit transfer direction is transmitted to target slave device, the master can know whether the slave acknowledged or not in the 9th high period of SCL1. If the master gains bus mastership, I2C generates GCALL interrupt regardless of the reception of ACK from the slave device. When I2C loses bus mastership during arbitration process, the MLOST1 bit in USI1ST2 is set, and I2C waits in idle state or can be operate as an addressed slave. To operate as a slave when the MLOST1 bit in USI1ST2 is set, the ACK1EN bit in USI1CR4 must be set and the received 7-bit address must equal to the USI1SLA[6:0] bits in USI1SAR. In this case I2C operates as a slave transmitter or a slave receiver (go to appropriate section). In this stage, I2C holds the SCL1 LOW. This is because to decide whether I2C continues serial transfer or stops communication. The following steps continue assuming that I2C does not lose mastership during first data transfer.

I2C (Master) can choose one of the following cases regardless of the reception of ACK signal from slave.

- 1) Master receives ACK signal from slave, so continues data transfer because slave can receive more data from master. In this case, load data to transmit to USI1DR.
- 2) Master stops data transfer even if it receives ACK signal from slave. In this case, set the STOPC1 bit in USI1CR4.
- 3) Master transmits repeated START condition with not checking ACK signal. In this case, load SLA1+R/W into the USI1DR and set STARTC1 bit in USI1CR4.

After doing one of the actions above, write any arbitrary to USI1ST2 to release SCL1 line. In case of 1), move to step 7. In case of 2), move to step 9 to handle STOP interrupt. In case of 3), move to step 6 after transmitting the data in USI1DR and if transfer direction bit is '1' go to master receiver section.

16. 1-Byte of data is being transmitted. During data transfer, bus arbitration continues.
17. This is ACK signal processing stage for data packet transmitted by master. I2C holds the SCL1 LOW. When I2C loses bus mastership while transmitting data arbitrating other masters, the MLOST1 bit in USI1ST2 is set. If then, I2C waits in idle state. When the data in USI1DR is transmitted completely, I2C generates TEND1 interrupt.

I2C can choose one of the following cases regardless of the reception of ACK signal from slave.

- 1) Master receives ACK signal from slave, so continues data transfer because slave can receive more data from master. In this case, load data to transmit to USI1DR.
- 2) Master stops data transfer even if it receives ACK signal from slave. In this case, set the STOPC1 bit in USI1CR4.
- 3) Master transmits repeated START condition with not checking ACK signal. In this case, load SLA1+R/W into the USI1DR and set the STARTC1 bit in USI1CR4.

After doing one of the actions above, write any arbitrary to USI1ST2 to release SCL1 line. In case of 1), move to step 7. In case of 2), move to step 9 to handle STOP interrupt. In case of 3), move to step 6 after transmitting the data in USI1DR, and if transfer direction bit is '1' go to master receiver section.

18. This is the final step for master transmitter function of I2C, handling STOP interrupt. The STOP bit indicates that data transfer between master and slave is over. To clear USI1ST2, write any value to USI1ST2. After this, I2C enters idle state.

The flowchart illustrates the I2C protocol communication between a Master and a Slave. It details the sequence of events from address recognition to data transfer and error handling.

Legend:

- Gray Box:** From master to slave / Master command or Data Write
- White Box:** From slave to master
- Circle (0xxx):** Value of Status Register
- Diamond (ACK):** Interrupt, SCL1 line is held low
- Box (P):** Interrupt after stop command
- Box (LOST&):** Arbitration lost as master and addressed as slave

Master Receiver Sequence:

- Master Receiver receives data from **SLA+R** (Slave Address + Read) and **S or Sr** (Start or Stop).
- Master Receiver sends **SLA+W** (Slave Address + Write) to the Slave.
- Master Receiver checks for **ACK** (Acknowledge) from the Slave.
 - If **ACK** is received (Y), the Master Receiver proceeds to the **DATA** block.
 - If **ACK** is not received (N), the Master Receiver sends a **STOP** command (Status Register 0x86) and then a **P** (Interrupt after stop command) signal (Status Register 0x22).

Slave Receiver Sequence:

- Slave Receiver receives data from **SLA+W** (Slave Address + Write) and **S or Sr** (Start or Stop).
- Slave Receiver checks for **ACK** (Acknowledge) from the Master.
 - If **ACK** is received (Y), the Slave Receiver proceeds to the **DATA** block.
 - If **ACK** is not received (N), the Slave Receiver sends a **STOP** command (Status Register 0x46) and then a **P** (Interrupt after stop command) signal (Status Register 0x22).

Data Transfer and Error Handling:

- DATA:** Data transfer block. If **ACK** is received (Y), the Master Receiver proceeds to the **Cont?** (Continue?) decision.
- Rs:** Read Slave block. If **ACK** is received (Y), the Master Receiver proceeds to the **Cont?** (Continue?) decision.
- STOP:** Stop command block. If **ACK** is received (Y), the Master Receiver proceeds to the **Cont?** (Continue?) decision.
- LOST:** Arbitration lost block. If **ACK** is received (Y), the Master Receiver proceeds to the **Cont?** (Continue?) decision.
- LOST&:** Arbitration lost as master and addressed as slave block. If **ACK** is received (Y), the Master Receiver proceeds to the **Cont?** (Continue?) decision.
- Cont? (Continue?):** Decision block. If **Y** (Yes), the Master Receiver proceeds to the **DATA** block. If **N** (No), the Master Receiver sends a **STOP** command (Status Register 0x47) and then a **P** (Interrupt after stop command) signal (Status Register 0x22).

Other master continues: If the Master Receiver receives a **STOP** command (Status Register 0x46) and a **P** (Interrupt after stop command) signal (Status Register 0x22), it sends a **STOP** command (Status Register 0x0E) and then a **P** (Interrupt after stop command) signal (Status Register 0x0F).

Slave Receiver (0x1D) or Transmitter (0x1F): If the Slave Receiver receives a **STOP** command (Status Register 0x0F) and a **P** (Interrupt after stop command) signal (Status Register 0x22), it sends a **STOP** command (Status Register 0x0E) and then a **P** (Interrupt after stop command) signal (Status Register 0x0F).

PS029902-0212

11.13.20.2 USI1 I2C Master Receiver

To operate I2C in master receiver, follow the recommended steps below.

10. Enable I2C by setting USI1MS[1:0] bits in USI1CR1 and USI1EN bit in USI1CR2. This provides main clock to the peripheral.
11. Load SLA1+R into the USI1DR where SLA is address of slave device and R is transfer direction from the viewpoint of the master. For master receiver, R is '1'. Note that USI1DR is used for both address and data.
12. Configure baud rate by writing desired value to both USI1SCLR and USI1SCHR for the Low and High period of SCL1 line.
13. Configure the USI1SDHR to decide when SDA1 changes value from falling edge of SCL1. If SDA1 should change in the middle of SCL1 LOW period, load half the value of USI1SCLR to the USI1SDHR.
14. Set the STARTC1 bit in USI1CR4. This transmits a START condition. And also configure how to handle interrupt and ACK signal. When the STARTC1 bit is set, 8-bit data in USI1DR is transmitted out according to the baud-rate.
15. This is ACK signal processing stage for address packet transmitted by master. When 7-bit address and 1-bit transfer direction is transmitted to target slave device, the master can know whether the slave acknowledged or not in the 9th high period of SCL1. If the master gains bus mastership, I2C generates GCALL interrupt regardless of the reception of ACK from the slave device. When I2C loses bus mastership during arbitration process, the MLOST1 bit in USI1ST2 is set, and I2C waits in idle state or can be operate as an addressed slave. To operate as a slave when the MLOST1 bit in USI1ST2 is set, the ACK1EN bit in USI1CR4 must be set and the received 7-bit address must equal to the USI1SLA[6:0] bits in USI1SAR. In this case I2C operates as a slave transmitter or a slave receiver (go to appropriate section). In this stage, I2C holds the SCL1 LOW. This is because to decide whether I2C continues serial transfer or stops communication. The following steps continue assuming that I2C does not lose mastership during first data transfer.

I2C (Master) can choose one of the following cases according to the reception of ACK signal from slave.

- 1) Master receives ACK signal from slave, so continues data transfer because slave can prepare and transmit more data to master. Configure ACK0EN bit in USI0CR4 to decide whether I2C ACKnowledges the next data to be received or not.
- 2) Master stops data transfer because it receives no ACK signal from slave. In this case, set the STOPC1 bit in USI1CR4.
- 3) Master transmits repeated START condition due to no ACK signal from slave. In this case, load SLA1+R/W into the USI1DR and set STARTC1 bit in USI1CR4.

After doing one of the actions above, write arbitrary value to USI1ST2 to release SCL1 line. In case of 1), move to step 7. In case of 2), move to step 9 to handle STOP interrupt. In case of 3), move to step 6 after transmitting the data in USI1DR and if transfer direction bit is '0' go to master transmitter section.

16. 1-Byte of data is being received.
17. This is ACK signal processing stage for data packet transmitted by slave. I2C holds the SCL1 LOW. When 1-Byte of data is received completely, I2C generates TEND1 interrupt.

I2C can choose one of the following cases according to the RXACK1 flag in USI1ST2.

- 1) Master continues receiving data from slave. To do this, set ACK1EN bit in USI0CR4 to ACKnowledge the next data to be received.
- 2) Master wants to terminate data transfer when it receives next data by not generating ACK signal. This can be done by clearing ACK1EN bit in USI1CR4.
- 3) Because no ACK signal is detected, master terminates data transfer. In this case, set the STOPC1 bit in USI1CR4.
- 4) No ACK signal is detected, and master transmits repeated START condition. In this case, load SLA1+R/W into the USI1DR and set the STARTC1 bit in USI1CR4.

After doing one of the actions above, write arbitrary value to USI1ST2 to release SCL1 line. In case of 1) and 2), move to step 7. In case of 3), move to step 9 to handle STOP interrupt. In case of 4), move to step 6 after transmitting the data in USI1DR, and if transfer direction bit is '0' go to master transmitter section.

- The processes described above for master receiver operation of I2C can be depicted as the following figure.

11.13.20.3 USI1 I2C Slave Transmitter

To operate I2C in slave transmitter, follow the recommended steps below.

8. If the main operating clock (SCLK) of the system is slower than that of SCL1, load value 0x00 into USI1SDHR to make SDA1 change within one system clock period from the falling edge of SCL1. Note that the hold time of SDA1 is calculated by SDAH x period of SCLK where SDAH is multiple of number of SCLK coming from USI1SDHR. When the hold time of SDA1 is longer than the period of SCLK, I2C (slave) cannot transmit serial data properly.
9. Enable I2C by setting USI1MS[1:0] bits in USI1CR1, IIC1IE bit in USI1CR4 and USI1EN bit in USI1CR2. This provides main clock to the peripheral.
10. When a START condition is detected, I2C receives one byte of data and compares it with USI1SLA[6:0] bits in USI1SAR. If the GCALL1 bit in USI1SAR is enabled, I2C compares the received data with value 0x00, the general call address.
11. If the received address does not equal to USI1SLA[6:0] bits in USI1SAR, I2C enters idle state ie, waits for another START condition. Else if the address equals to USI1SLA[6:0] bits and the ACK1EN bit is enabled, I2C generates SSEL1 interrupt and the SCL1 line is held LOW. Note that even if the address equals to USI1SLA[6:0] bits, when the ACK1EN bit is disabled, I2C enters idle state. When SSEL1 interrupt occurs, load transmit data to USI1DR and write arbitrary value to USI1ST2 to release SCL1 line.
12. 1-Byte of data is being transmitted.
13. In this step, I2C generates TEND1 interrupt and holds the SCL1 line LOW regardless of the reception of ACK signal from master. Slave can select one of the following cases.
 - 1) No ACK signal is detected and I2C waits STOP or repeated START condition.
 - 2) ACK signal from master is detected. Load data to transmit into USI1DR.

After doing one of the actions above, write arbitrary value to USI1ST2 to release SCL1 line. In case of 1) move to step 7 to terminate communication. In case of 2) move to step 5. In either case, a repeated START condition can be detected. For that case, move step 4.

14. This is the final step for slave transmitter function of I2C, handling STOP interrupt. The STOPC1 bit indicates that data transfer between master and slave is over. To clear USI1ST2, write any value to USI1ST2. After this, I2C enters idle state.

The next figure shows flow chart for handling slave transmitter function of I2C.

Figure 11.96 Formats and States in the Slave Transmitter Mode (US11)

11.13.20.4 USI1 I2C Slave Receiver

To operate I2C in slave receiver, follow the recommended steps below.

8. If the main operating clock (SCLK) of the system is slower than that of SCL1, load value 0x00 into USI1SDHR to make SDA1 change within one system clock period from the falling edge of SCL1. Note that the hold time of SDA1 is calculated by SDAH x period of SCLK where SDAH is multiple of number of SCLK coming from USI1SDHR. When the hold time of SDA1 is longer than the period of SCLK, I2C (slave) cannot transmit serial data properly.
9. Enable I2C by setting USI1MS[1:0] bits in USI1CR1, IIC1IE bit in USI1CR4 and USI1EN bit in USI1CR2. This provides main clock to the peripheral.
10. When a START condition is detected, I2C receives one byte of data and compares it with USI1SLA[6:0] bits in USI1SAR. If the GCALL1 bit in USI1SAR is enabled, I2C1 compares the received data with value 0x00, the general call address.
11. If the received address does not equal to SLA1 bits in USI1SAR, I2C enters idle state ie, waits for another START condition. Else if the address equals to SLA1 bits and the ACK1EN bit is enabled, I2C generates SSEL1 interrupt and the SCL1 line is held LOW. Note that even if the address equals to SLA1 bits, when the ACK1EN bit is disabled, I2C enters idle state. When SSEL1 interrupt occurs and I2C is ready to receive data, write arbitrary value to USI1ST2 to release SCL1 line.
12. 1-Byte of data is being received.
13. In this step, I2C generates TEND1 interrupt and holds the SCL1 line LOW regardless of the reception of ACK signal from master. Slave can select one of the following cases.
 - 1) No ACK signal is detected (ACK1EN=0) and I2C waits STOP or repeated START condition.
 - 2) ACK signal is detected (ACK1EN=1) and I2C can continue to receive data from master.

After doing one of the actions above, write arbitrary value to USI1ST2 to release SCL1 line. In case of 1) move to step 7 to terminate communication. In case of 2) move to step 5. In either case, a repeated START condition can be detected. For that case, move step 4.

14. This is the final step for slave receiver function of I2C, handling STOP interrupt. The STOPC1 bit indicates that data transfer between master and slave is over. To clear USI1ST2, write any value to USI1ST2. After this, I2C enters idle state.

The process can be depicted as following figure when I2C operates in slave receiver mode.

Figure 11.97 Formats and States in the Slave Receiver Mode (USI1)

11.13.21 USI1 I2C Block Diagram

NOTE) When the USI1 block is an I2C mode and the corresponding port is an sub-function for SCL1/SDA1 pin, the SCL1/SDA1 pins are automatically set to the N-channel open-drain outputs and the input latch is read in the case of reading the pins. The corresponding pull-up resistor is determined by the control register.

11.13.23 USI1 Register Description

USI1 module consists of USI1 baud rate generation register (USI1BD), USI1 data register (USI1DR), USI1 SDA hold time register (USI1SDHR), USI1 SCL high period register (USI1SCHR), USI1 SCL low period Register (USI1SCLR), USI1 slave address register (USI1SAR), USI1 control register 1/2/3/4 (USI1CR1/2/3/4), USI1 status register 1/2 (USI1ST1/2).

11.13.24 Register Description for USI1

USI1BD (USI1 Baud- Rate Generation Register: For UART and SPI mode) : F3H

7	6	5	4	3	2	1	0
USI1BD7	USI1BD6	USI1BD5	USI1BD4	USI1BD3	USI1BD2	USI1BD1	USI1BD0
RW	RW	RW	RW	RW	RW	RW	RW

Initial value : FFH

USI1BD[7:0]

The value in this register is used to generate internal baud rate in asynchronous mode or to generate SCK1 clock in SPI mode. To prevent malfunction, do not write '0' in asynchronous mode and do not write '0' or '1' in SPI mode.

(NOTE) In common with USI1SAR register, USI1BD register is used for slave address register when the USI1 I2C mode.

USI1DR (USI1 Data Register: For UART, SPI, and I2C mode) : F5H

7	6	5	4	3	2	1	0
USI1DR7	USI1DR6	USI1DR5	USI1DR4	USI1DR3	USI1DR2	USI1DR1	USI1DR0
RW	RW	RW	RW	RW	RW	RW	RW

Initial value : 00H

USI1DR[7:0] The USI1 transmit buffer and receive buffer share the same I/O address with this DATA register. The transmit data buffer is the destination for data written to the USI1DR register. Reading the USI1DR register returns the contents of the receive buffer.
Write to this register only when the DRE1 flag is set. In SPI master mode, the SCK1 clock is generated when data are written to this register.

USI1SDHR (USI1 SDA Hold Time Register: For I2C mode) : F4H

7	6	5	4	3	2	1	0
USI1SDHR7	USI1SDHR6	USI1SDHR5	USI1SDHR4	USI1SDHR3	USI1SDHR2	USI1SDHR1	USI1SDHR0
RW	RW	RW	RW	RW	RW	RW	RW

Initial value : 00H

USI1SDHR[7:0] The register is used to control SDA1 output timing from the falling edge of SCL1 in I2C mode.
NOTE) That SDA1 is changed after $t_{SCLK} \times (USI1SDHR+2)$, in master SDA1 change in the middle of SCL1.
In slave mode, configure this register regarding the frequency of SCL1 from master.
The SDA1 is changed after $t_{sclk} \times (USI1SDHR+2)$ in master mode. So, to insure operation in slave mode, the value $t_{SCLK} \times (USI1SDHR + 2)$ must be smaller than the period of SCL1.

USI1SCHR (USI1 SCL High Period Register: For I2C mode) : F7H

7	6	5	4	3	2	1	0
USI1SCHR7	USI1SCHR6	USI1SCHR5	USI1SCHR4	USI1SCHR3	USI1SCHR2	USI1SCHR1	USI1SCHR0
RW	RW	RW	RW	RW	RW	RW	RW

Initial value : 00H

USI1SCHR[7:0] This register defines the high period of SCL1 when it operates in I2C master mode.
The base clock is SCLK, the system clock, and the period is calculated by the formula: $t_{SCLK} \times (4 \times USI1SCHR + 2)$ where t_{SCLK} is the period of SCLK.

So, the operating frequency of I2C master mode is calculated by the following equation.

$$f_{I2C} = \frac{1}{t_{SCLK} \times (4 \times (USI1SCLR + USI1SCHR + 4))}$$

USI1SCLR (USI1 SCL Low Period Register: For I2C mode) : F6H

7	6	5	4	3	2	1	0
USI1SCLR7	USI1SCLR6	USI1SCLR5	USI1SCLR4	USI1SCLR3	USI1SCLR2	USI1SCLR1	USI1SCLR0
RW	RW	RW	RW	RW	RW	RW	RW

Initial value : 00H

USI1SCLR[7:0] This register defines the high period of SCL1 when it operates in I2C master mode.
The base clock is SCLK, the system clock, and the period is calculated by the formula: $t_{SCLK} \times (4 \times USI1SCLR + 2)$ where t_{SCLK} is the period of SCLK.

USI1SAR (USI1 Slave Address Register: For I2C mode) : EDH

7	6	5	4	3	2	1	0
USI1SLA6	USI1SLA5	USI1SLA4	USI1SLA3	USI1SLA2	USI1SLA1	USI1SLA0	USI1GCE
RW	RW	RW	RW	RW	RW	RW	RW

Initial value : 00H

USI1SLA[6:0] These bits configure the slave address of I2C when it operates in I2C slave mode.

UPM[1:0] This bit decides whether I2C allows general call address or not in I2C slave mode.

- 0 Ignore general call address
- 1 Allow general call address

USI1CR1 (USI1 Control Register 1: For UART, SPI, and I2C mode) : E9H

7	6	5	4	3	2	1	0
USI1MS1	USI1MS0	USI1PM1	USI1PM0	USI1S2	USI1S1 ORD1	USI1S0 CPHA1	CPOL1
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Initial value : 00H

USI1MS[1:0]	Selects operation mode of USI1			
	USI1MS1	USI1MS0	Operation mode	
	0 0		Asynchronous Mode (UART)	
	0 1		Synchronous Mode	
	1 0		I2C mode	
	1 1		SPI mode	
USI1PM[1:0]	Selects parity generation and check methods (only UART mode)			
	USI1PM1	USI1PM0	Parity	
	0 0		No Parity	
	0 1		Reserved	
	1 0		Even Parity	
	1 1		Odd Parity	
USI1S[2:0]	When in asynchronous or synchronous mode of operation, selects the length of data bits in frame			
	USI1S2	USI1S1	S1	USI1S0 Data Length
	0 0			0 5 bit
	0 0			1 6 bit
	0 1			0 7 bit
	0 1			1 8 bit
	1 0			0 Reserved
	1 0			1 Reserved
	1 1			0 Reserved
	1 1			1 9 bit
ORD1	This bit in the same bit position with USI1S1. The MSB of the data byte is transmitted first when set to '1' and the LSB when set to '0' (only SPI mode)			
	0	LS	B-first	
	1	MSB-	first	
CPOL1	This bit determines the clock polarity of ACK in synchronous or SPI mode.			
	0	TXD change@Rising Edge, RXD change@Falling Edge		
	1	TXD change@Falling Edge, RXD change@Rising Edge		
CPHA1	This bit is in the same bit position with USI1S0. This bit determines if data are sampled on the leading or trailing edge of SCK 1 (only SPI mode).			
	CPOL1	CPHA1	Leading edge	Trailing edge
	0	0	Sample (Rising)	Setup (Falling)
	0	1	Setup (Rising)	Sample (Falling)
	1	0	Sample (Falling)	Setup (Rising)
	1	1	Setup (Falling)	Sample (Rising)

USI1CR2 (USI1 Control Register 2: For UART, SPI, and I2C mode) : EAH

7	6	5	4	3	2	1	0
DRIE1	TXCIE1	RXCIE1	WAKEIE1	TXE1	RXE1	USI1EN	DBLS1
RW	RW	RW	RW	RW	RW	RW	RW

Initial value : 00H

DRIE1	Interrupt enable bit for data register empty (only UART and SPI mode). 0 Interrupt from DRE1 is inhibited (use polling) 1 When DRE1 is set, request an interrupt
TXCIE1	Interrupt enable bit for transmit complete (only UART and SPI mode). 0 Interrupt from TXC1 is inhibited (use polling) 1 When TXC1 is set, request an interrupt
RXCIE1	Interrupt enable bit for receive complete (only UART and SPI mode). 0 Interrupt from RXC1 is inhibited (use polling) 1 When RXC1 is set, request an interrupt
WAKEIE1	Interrupt enable bit for asynchronous wake in STOP mode. When device is in stop mode, if RXD1 goes to low level an interrupt can be requested to wake-up system. (only UART mode). At that time the DRIE1 bit and USI1ST1 register value should be set to '0b' and "00H", respectively. 0 Interrupt from Wake is inhibited 1 When WAKE1 is set, request an interrupt
TXE1	Enables the transmitter unit (only UART and SPI mode). 0 Transmitter is disabled 1 Transmitter is enabled
RXE1	Enables the receiver unit (only UART and SPI mode). 0 Receiver is disabled 1 Receiver is enabled
USI1EN	Activate USI1 function block by supplying. 0 USI1 is disabled 1 USI1 is enabled
DBLS1	This bit selects receiver sampling rate (only UART) 0 Normal asynchronous operation 1 Double Speed asynchronous operation

USI1CR3 (USI1 Control Register 3: For UART, SPI, and I2C mode) : EBH

7	6	5	4	3	2	1	0
MASTER1	LOOPS1	DISSCK1	USI1SSEN	FXCH1	USI1SB	USI1TX8	USI1RX8
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R

Initial value : 00H

MASTER1	Selects master or slave in SPI and synchronous mode operation and controls the direction of SCK1 pin 0 Slave mode operation (External clock for SCK1). 1 Master mode operation (Internal clock for SCK1).
LOOPS1	Controls the loop back mode of USI1 for test mode (only UART and SPI mode) 0 Normal operation 1 Loop Back mode
DISSCK1	In synchronous mode of operation, selects the waveform of SCK1 output 0 ACK is free-running while UART is enabled in synchronous master mode 1 ACK is active while any frame is on transferring
USI1SSEN	This bit controls the SS1 pin operation (only SPI mode) 0 Disable 1 Enable (The SS1 pin should be a normal input)
FXCH1	SPI port function exchange control bit (only SPI mode) 0 No effect 1 Exchange MOSI1 and MISO1 function
USI1SB	Selects the length of stop bit in asynchronous or synchronous mode of operation. 0 1 Stop Bit 1 2 Stop Bit
USI1TX8	The ninth bit of data frame in asynchronous or synchronous mode of operation. Write this bit first before loading the USI1DR register 0 MSB (9 th bit) to be transmitted is '0' 1 MSB (9 th bit) to be transmitted is '1'
USI1RX8	The ninth bit of data frame in asynchronous or synchronous mode of operation. Read this bit first before reading the receive buffer (only UART mode). 0 MSB (9 th bit) received is '0' 1 MSB (9 th bit) received is '1'

USI1CR4 (USI1 Control Register 4: For I2C mode) : ECH

7	6	5	4	3	2	1	0
IIC1IFR	–	TXDLYENB1	IIC1IE	ACK1EN	IMASTER1	STOPC1	STARTC1
R	–	RW	RW	RW	R	RW	RW

Initial value : 00H

IIC1IFR	This is an interrupt flag bit for I2C mode. When an interrupt occurs, this bit becomes '1'. This bit is cleared when write any values in th USI1ST2. 0 I2C interrupt no generation 1 I2C interrupt generation
TXDLYENB1	USI1SDHR register control bit 0 Enable USI1SDHR register 1 Disable USI1SDHR register
IIC1IE	Interrupt Enable bit for I2C mode 0 Interrupt from I2C is inhibited (use polling) 1 Enable interrupt for I2C
ACK1EN	Controls ACK signal Generation at ninth SCL1 period. 0 No ACK signal is generated (SDA1 =1) 1 ACK signal is generated (SDA1 =0) NOTES) ACK signal is output (SDA1 =0) for the following 3 cases. 1. When received address packet equals to USI1SLA bits in USI1SAR. 2. When received address packet equals to value 0x00 with GC ALL1 enabled. 3. When I2C operates as a receiver (master or slave)
IMASTER1	Represent operating mode of I2C 0 I2C is in slave mode 1 I2C is in master mode
STOPC1	When I2C is master, STOP condition generation 0 No effect 1 STOP condition is to be generated
STARTC1	When I2C is master, START condition generation 0 No effect 1 START or repeated START condition is to be generated

USI1ST1 (USI1 Status Register 1: For UART and SPI mode) : F1H

7	6	5	4	3	2	1	0
DRE1	TXC1	RXC1	WAKE1	USI1RST	DOR1	FE1	PE1
RW	RW	R	RW	RW	R	RW	RW

Initial value : 80H

DRE1	The DRE1 flag indicates if the transmit buffer (USI1DR) is ready to receive new data. If DRE1 is '1', the buffer is empty and ready to be written. This flag can generate a DRE1 interrupt. 0 Transmit buffer is not empty. 1 Transmit buffer is empty.
TXC1	This flag is set when the entire frame in the transmit shift register has been shifted out and there is no new data currently present in the transmit buffer. This flag is automatically cleared when the interrupt service routine of a TXC1 interrupt is executed. This flag can generate a TXC1 interrupt. This bit is automatically cleared. 0 Transmission is ongoing. 1 Transmit buffer is empty and the data in transmit shift register are shifted out completely.
RXC1	This flag is set when there are unread data in the receive buffer and cleared when all the data in the receive buffer are read. The RXC1 flag can be used to generate a RXC1 interrupt. 0 There is no data unread in the receive buffer 1 There are more than 1 data in the receive buffer
WAKE1	This flag is set when the RXD1 pin is detected low while the CPU is in STOP mode. This flag can be used to generate a WAKE1 interrupt. This bit is set only when in asynchronous mode of operation. This bit should be cleared by program software. (only UART mode) 0 No WAKE interrupt is generated. 1 WAKE interrupt is generated
USI1RST	This is an internal reset and only has effect on USI1. Writing '1' to this bit initializes the internal logic of USI1 and this bit is automatically cleared to '0'. 0 No operation 1 Reset USI1
DOR1	This bit is set if a Data OverRun occurs. While this bit is set, the incoming data frame is ignored. This flag is valid until the receive buffer is read. 0 No Data OverRun 1 Data OverRun detected
FE1	This bit is set if the first stop bit of next character in the receive buffer is detected as '0'. This bit is valid until the receive buffer is read. (only UART mode) 0 No Frame Error 1 Frame Error detected
PE1	This bit is set if the next character in the receive buffer has a Parity Error to be received while Parity Checking is enabled. This bit is valid until the receive buffer is read. (only UART mode) 0 No Parity Error 1 Parity Error detected

USI1ST2 (USI1 Status Register 2: For I2C mode) : F2H

7	6	5	4	3	2	1	0
GCALL1	TEND1	STOPD1	SSEL1	MLOST1	BUSY1	TMODE1	RXACK1
R	RW	RW	RW	RW	RW	RW	RW

Initial value : 00H

GCALL1^(NOTE) This bit has different meaning depending on whether I2C is master or slave. When I2C is a master, this bit represents whether it received AACK (address ACK) from slave.

0 No AACK is received (Master mode)

1 AACK is received (Master mode)

When I2C is a slave, this bit is used to indicate general call.

0 General call address is not detected (Slave mode)

1 General call address is detected (Slave mode)

TEND1^(NOTE) This bit is set when 1-byte of data is transferred completely

0 1 byte of data is not completely transferred

1 1 byte of data is completely transferred

STOPD1^(NOTE) This bit is set when a STOP condition is detected.

0 No STOP condition is detected

1 STOP condition is detected

SSEL1^(NOTE) This bit is set when I2C is addressed by other master.

0 I2C is not selected as a slave

1 I2C is addressed by other master and acts as a slave

MLOST1^(NOTE) This bit represents the result of bus arbitration in master mode.

0 I2C maintains bus mastership

1 I2C maintains bus mastership during arbitration process

BUSY1 This bit reflects bus status.

0 I2C bus is idle, so a master can issue a START condition

1 I2C bus is busy

TMODE1 This bit is used to indicate whether I2C is transmitter or receiver.

0 I2C is a receiver

1 I2C is a transmitter

RXACK1 This bit shows the state of ACK signal

0 No ACK is received

1 ACK is received at ninth SCL period

NOTE) These bits can be source of interrupt.

When an I2C interrupt occurs except for STOP mode, the SCL1 line is held LOW. To release SCL1, write arbitrary value to USI1ST2. When USI1ST2 is written, the TEND1, STOPD1, SSEL1, MLOST1, and RXACK1 bits are cleared.

11.15 LCD Driver

11.15.1 Overview

The LCD driver is controlled by the LCD Control Register (LCDCRH/L). The LCLK[1:0] determines the frequency of COM signal scanning of each segment output. A RESET clears the LCD control register LCDCRH and LCDCRL values to logic '0'.

The LCD display can continue operating during IDLE and STOP modes if a sub-frequency clock is used as system clock source.

11.15.2 LCD Display RAM Organization

Display data are stored to the display data area in the external data memory.

The display data which stored to the display external data area (address 0000H-001AH) are read automatically and sent to the LCD driver by the hardware. The LCD driver generates the segment signals and common signals in accordance with the display data and drive method. Therefore, display patterns can be changed by only overwriting the contents of the display external data area with a program.

Figure 11-99 shows the correspondence between the display external data area and the COM/SEG pins. The LCD is turned on when the display data is "1" and turned off when "0".

Figure 11.99 LCD Circuit Block Diagram

LDCRHH 9AH		R/W	00H	LCD Driver Control High Register
LDCRHL 99H		R/W	00H	LCD Driver Control Low Register
LDCCCR	9BH	R/W	00H	LCD Contrast Control Register

11.15.7 LCD Driver Register Description

LCD driver register has two control registers, LCD driver control high register (LDCRHH), LCD driver control low register (LDCRHL) and LCD contrast control register.

11.15.8 Register Description for LCD Driver

LCDCRH (LCD Driver Control High Register) : 9AH

7	6	5	4	3	2	1	0
–	–	–	COMCHG	–	–	LCDDR	DISP
–	–	–	RW	–	–	RW	RW

Initial value : 00H

COMCHG Common Signal Output Port Change Control
0 COM0 – COM3 signals are outputted through the P37-P34
1 COM0 – COM3 signals are outputted through the P33-P30

NOTES)

1. The COM0/COM1/COM2/COM3 signals can be outputted through the P33/P32/P31/P30, respectively.
2. For example, the COM0 signal may be outputted to P33 pin if the P3FSR.3 is “1b” and the COMCHG bit is “1b”.
3. Refer to the port3 function selection register (P3FSR).
4. Available only below the 1/4 duty.

LCDDR LCD Driving Resistor for Bias Select

1 LCD Driver Contrast enable

VLCD[3:0] VLCD Voltage Control when the contrast is enabled

VLCD3	VLCD 2	VLCD 1	VLCD 0	Description
0	0	0 0	V	LC0 = VDD x 16/31 step
0	0	0 1	V	LC0 = VDD x 16/30 step
0	0	1 0	V	LC0 = VDD x 16/29 step
0	0	1 1	V	LC0 = VDD x 16/28 step
0	1	0 0	V	LC0 = VDD x 16/27 step
0	1	0 1	V	LC0 = VDD x 16/26 step
0	1	1 0	V	LC0 = VDD x 16/25 step
0	1	1 1	V	LC0 = VDD x 16/24 step
1	0	0 0	V	LC0 = VDD x 16/23 step
1	0	0 1	V	LC0 = VDD x 16/22 step
1	0	1 0	V	LC0 = VDD x 16/21 step
1	0	1 1	V	LC0 = VDD x 16/20 step
1	1	0 0	V	LC0 = VDD x 16/19 step
1	1	0 1	V	LC0 = VDD x 16/18 step
1	1	1 0	V	LC0 = VDD x 16/17 step
1	1	1 1	V	LC0 = VDD x 16/16 step

NOTES) The LCD contrast step is based on 1/4 bias.

1/4 bias : $VDD \times (16/31 - VLC[3:0])$

1/3 bias : $VDD \times (12/27 - VLC[3:0])$

1/2 bias : $VDD \times (8/23 - VLC[3:0])$

12. Power Down Operation

12.1 Overview

The Z51F3220 has two power-down modes to minimize the power consumption of the device. In power down mode, power consumption is reduced considerably. The device provides three kinds of power saving functions, Main-IDLE, Sub-IDLE and STOP mode. In three modes, program is stopped.

12.2 Peripheral Operation in IDLE/STOP Mode

Table 12-1 Peripheral Operation during Power Down Mode

Peripheral ID	LE Mode	STOP Mode
CPU	ALL CPU Operation are Disable	ALL CPU Operation are Disable
RAM R	Retain	Retain
Basic Interval Timer	Operates Continuously	Stop
Watch Dog Timer	Operates Continuously	Stop (Can be operated with WDTRC OSC)
Watch Timer	Operates Continuously	Stop (Can be operated with sub clock)
Timer0~4 O	Operates Continuously	Halted (Only when the Event Counter Mode is Enabled, Timer operates Normally)
ADC O	Operates Continuously	Stop
BUZ O	Operates Continuously	Stop
SPI	Operates Continuously	Only operate with external clock
USI0/1	Operates Continuously	Only operate with external clock
LCD Controller	Operates Continuously	Stop (Can be operated with sub clock)
Internal OSC (16MHz)	Oscillation	Stop when the system clock (fx) is firc
WDTRC OSC (5kHz)	Stop	Can be operated with setting value
Main OSC (0.4~12MHz)	Oscillation	Stop when fx = fxIN
Sub OSC (32.768kHz)	Oscillation	Stop when fx = fsUB
I/O Port	Retain	Retain
Control Register	Retain	Retain
Address Data Bus	Retain	Retain
Release Method	By RESET, all Interrupts	By RESET, Timer Interrupt (EC0, EC1, EC3), SPI (External clock), External Interrupt, UART by ACK, WT (sub clock), WDT

12.3 IDLE Mode

The power control register is set to '01h' to enter the IDLE Mode. In this mode, the internal oscillation circuits remain active. Oscillation continues and peripherals are operated normally but CPU stops. It is released by reset or interrupt. To be released by interrupt, interrupt should be enabled before IDLE mode. If using reset, because the device becomes initialized state, the registers have reset value.

Figure 12.1 IDLE Mode Release Timing by External Interrupt

12.4 STOP Mode

The power control register is set to '03H' to enter the STOP Mode. In the stop mode, the selected oscillator, system clock and peripheral clock is stopped, but watch timer can be continued to operate with sub clock. With the clock frozen, all functions are stopped, but the on-chip RAM and control registers are held. For example, If the internal RC oscillator (f_{IRC}) is selected for the system clock and the sub clock (f_{SUB}) is oscillated, the internal RC oscillator stops oscillation and the sub clock is continuously oscillated in stop mode. At that time, the watch timer and LCD controller can be operated with the sub clock.

The source for exit from STOP mode is hardware reset and interrupts. The reset re-defines all the control registers.

When exit from STOP mode, enough oscillation stabilization time is required to normal operation. Figure 12.2 shows the timing diagram. When released from STOP mode, the Basic interval timer is activated on wake-up. Therefore, before STOP instruction, user must be set its relevant prescale divide ratio to have long enough time. This guarantees that oscillator has started and stabilized.

Figure 12.2 STOP Mode Release Timing by External Interrupt

12.5 Release Operation of STOP Mode

After STOP mode is released, the operation begins according to content of related interrupt register just before STOP mode start (Figure 12.3). If the global interrupt Enable Flag (IE.EA) is set to '1', the STOP mode is released by the interrupt which each interrupt enable flag = '1' and the CPU jumps to the relevant interrupt service routine. Even if the IE.EA bit is cleared to '0', the STOP mode is released by the interrupt of which the interrupt enable flag is set to '1'.

Figure 12.3 STOP Mode Release Flow

13. RESET

13.1 Overview

The following is the hardware setting value.

Table 13-1 Reset State

On Chip Hardware	Initial Value
Program Counter (PC)	0000h
Accumulator 00h	
Stack Pointer (SP)	07h
Peripheral Clock	On
Control Register	Refer to the Peripheral Registers

13.2 Reset Source

The Z51F3220 has five types of reset sources. The following is the reset sources.

- External RESETB
- Power ON RESET (POR)
- WDT Overflow Reset (In the case of WDTEN = `1`)
- Low Voltage Reset (In the case of LVREN = `0`)
- OCD Reset

13.3 RESET Block Diagram

Figure 13.1 RESET Block Diagram

13.4 RESET Noise Canceller

The Figure 13.2 is the noise canceller diagram for noise cancellation of RESET. It has the noise cancellation value of about 2us (@V_{DD}=5V) to the low input of system reset.

Figure 13.2 Reset noise canceller timer diagram

13.5 Power on RESET

When rising device power, the POR (Power On Reset) has a function to reset the device. If POR is used, it executes the device RESET function instead of the RESET IC or the RESET circuits.

Figure 13.3 Fast VDD Rising Time

Figure 13.4 Internal RESET Release Timing On Power-Up

Table 13-2 Boot Process Description

Process	Description	Remarks
①	-No Operation	
②	-1st POR level Detection	-about 1.4V
③	- (INT-OSC 8MHz/8)x256x28h Delay section (=10ms) -VDD input voltage must rise over the flash operating voltage for Config read	-Slew Rate $\geq 0.15\text{V/ms}$
④	- Config read point	-about 1.5V ~ 1.6V -Config Value is determined by Writing Option
⑤	- Rising section to Reset Release Level	-16ms point after POR or Ext_reset release
⑥	- Reset Release section (BIT overflow) i) after 16ms, after External Reset Release (External reset) ii) 16ms point after POR (POR only)	- BIT is used for Peripheral stability
⑦	-Normal operation	

13.6 External RESETB Input

The External RESETB is the input to a Schmitt trigger. If RESETB pin is held with low for at least 10 μ s over within the operating voltage range and stable oscillation, it is applied and the internal state is initialized. After reset state becomes '1', it needs the stabilization time with 16ms and after the stable state, the internal RESET becomes '1'. The Reset process step needs 5 oscillator clocks. And the program execution starts at the vector address stored at address 0000H.

Figure 13.7 Timing Diagram after RESET

Figure 13.8 Oscillator generating waveform example

NOTE) As shown Figure 13.8, the stable generating time is not included in the start-up time.

The RESETB pin has a Pull-up register by H/W.

13.7 Brown Out Detector Processor

The Z51F3220 has an On-chip brown-out detection circuit (BOD) for monitoring the VDD level during operation by comparing it to a fixed trigger level. The trigger level for the BOD can be selected by LVRVS[3:0] bit to be 1.60V, 2.00V, 2.10V, 2.20V, 2.32V, 2.44V, 2.59V, 2.75V, 2.93V, 3.14V, 3.38V, 3.67V, 4.00V, 4.40V. In the STOP mode, this will contribute significantly to the total current consumption. So to minimize the current consumption, the LVREN bit is set to off by software.

13.8.1 Register Map

Table 13-3 Reset Operation Register Map

Name	Address	Dir	Default	Description
RSTFR E8H		R/W	80H	Reset Flag Register
LVRCD	8H	R/W	00H	Low Voltage Reset Control Register
LVICR	86H	R/W	00H	Low Voltage Indicator Control Register

13.8.2 Reset Operation Register Description

The reset control register consists of the reset flag register (RSTFR), low voltage reset control register (LVRCD), and low voltage indicator control register (LVICR).

13.8.3 Register Description for Reset Operation

RSTFR (Reset Flag Register) : E8H

7	6	5	4	3	2	1	0
PORF	EXTRF	WDTRF	OCDRF	LVRF	—	—	—
RW	RW	RW	RW	RW	—	—	—

Initial value : 80H

PORF	Power-On Reset flag bit. The bit is reset by writing '0' to this bit. 0 No detection 1 Detection
EXTRF	External Reset (RESETB) flag bit. The bit is reset by writing '0' to this bit or by Power-On Reset. 0 No detection 1 Detection
WDTRF	Watch Dog Reset flag bit. The bit is reset by writing '0' to this bit or by Power-On Reset. 0 No detection 1 Detection
OCDRF	On-Chip Debug Reset flag bit. The bit is reset by writing '0' to this bit or by Power-On Reset. 0 No detection 1 Detection
LVRF	Low Voltage Reset flag bit. The bit is reset by writing '0' to this bit or by Power-On Reset. 0 No detection 1 Detection

- NOTES) 1. When the Power-On Reset occurs, the PORF bit is only set to "1", the other flag (WDTRF and OCDRF) bits are all cleared to "0".
2. When the Power-On Reset occurs, the EXTRF bit is unknown, At that time, the EXTRF bit can be set to "1" when External Reset (RESETB) occurs.
3. When the Power-On Reset occurs, the LVRF bit is unknown, At that time, the LVRF bit can be set to "1" when LVR Reset occurs.
4. When a reset except the POR occurs, the corresponding flag bit is only set to "1", the other flag bits are kept in the previous values.

LVRCCR (Low Voltage Reset Control Register) : D8H

14. On-chip Debug System

14.1 Overview

14.1.1 Description

On-chip debug system (OCD) of Z51F3220 can be used for programming the non-volatile memories and on-chip debugging. Detail descriptions for programming via the OCD interface can be found in the following chapter.

Figure 14.1 shows a block diagram of the OCD interface and the On-chip Debug system.

14.1.2 Feature

- Two-wire external interface: 1-wire serial clock input, 1-wire bi-directional serial data bus
- Debugger Access to:
 - All Internal Peripheral Units
 - Internal data RAM
 - Program Counter
 - Flash and Data EEPROM Memories
- Extensive On-chip Debug Support for Break Conditions, Including
 - Break Instruction
 - Single Step Break
 - Program Memory Break Points on Single Address
 - Programming of Flash, EEPROM, Fuses, and Lock Bits through the two-wire Interface
 - On-chip Debugging Supported by Dr.Choice®
- Operating frequency
 - Supports the maximum frequency of the target MCU

Figure 14.1 Block Diagram of On-Chip Debug System

14.2 Two-Pin External Interface

14.2.1 Basic Transmission Packet

- 10-bit packet transmission using two-pin interface.
- 1-packet consists of 8-bit data, 1-bit parity and 1-bit acknowledge.
- Parity is even of '1' for 8-bit data in transmitter.
- Receiver generates acknowledge bit as '0' when transmission for 8-bit data and its parity has no error.
- When transmitter has no acknowledge (Acknowledge bit is '1' at tenth clock), error process is executed in transmitter.
- When acknowledge error is generated, host PC makes stop condition and transmits command which has error again.
- Background debugger command is composed of a bundle of packet.
- Start condition and stop condition notify the start and the stop of background debugger command respectively.

Figure 14.2 10-bit Transmission Packet

14.2.2 Packet Transmission Timing

14.2.2.1 Data Transfer

Figure 14.7 Clock Synchronization during Wait Procedure

14.2.3 Connection of Transmission

Two-pin interface connection uses open-drain (wire-AND bidirectional I/O).

Figure 14.8 Connection of Transmission

15. Flash Memory

15.1 Overview

15.1.1 Description

Z51F3220 incorporates flash memory to which a program can be written, erased, and overwritten while mounted on the board. The flash memory can be read by 'MOVC' instruction and it can be programmed in OCD, serial ISP mode or user program mode.

- Flash Size : 32kbytes
- Single power supply program and erase
- Command interface for fast program and erase operation
- Up to 100,000 program/erase cycles at typical voltage and temperature for flash memory

15.1.2 Flash Program ROM Structure

Figure 15.1 Flash Program ROM Structure

15.1.3 Register Map

Table 15-1Flash Memory Register Map

Name	Address	Dir	Default	Description
FSADRH	FAH	R/W	00H	Flash Sector Address High Register
FSADRM	FBH	R/W	00H	Flash Sector Address Middle Register
FSADRL	FCH	R/W	00H	Flash Sector Address Low Register
FIDR	FDH	R/W	00H	Flash Identification Register
FMCR	FEH	R/W	00H	Flash Mode Control Register

15.1.4 Register Description for Flash Memory Control and Status

Flash control register consists of the flash sector address high register (FSADRH), flash sector address middle register (FSADRM), flash sector address low register (FSADRL), flash identification register (FIDR), and flash mode control register (FMCR). They are mapped to SFR area and can be accessed only in programming mode.

15.1.5 Register Description for Flash

FSADRH (Flash Sector Address High Register) : FAH

7	6	5	4	3	2	1	0
–	–	–	–	FSADRH3	FSADRH2	FSADRH1	FSADRH0
–	–	–	–	RW	RW	RW	RW

Initial value : 00H

FSADRH[3:0] Flash Sector Address High

FSADRM (Flash Sector Address Middle Register) : FBH

7	6	5	4	3	2	1	0
FSADRM7	FSADRM6	FSADRM5	FSADRM4	FSADRM3	FSADRM2	FSADRM1	FSADRM0
RW	RW	RW	RW	RW	RW	RW	RW

Initial value : 00H

FSADRM[7:0] Flash Sector Address Middle

FSADRL (Flash Sector Address Low Register) : FCH

7	6	5	4	3	2	1	0
FSADRL7	FSADRL6	FSADRL5	FSADRL4	FSADRL3	FSADRL2	FSADRL1	FSADRL0
RW	RW	RW	RW	RW	RW	RW	RW

Initial value : 00H

FSADRL[7:0] Flash Sector Address Low

FIDR (Flash Identification Register) : FDH

7	6	5	4	3	2	1	0
FIDR7	FIDR6	FIDR5	FIDR4	FIDR3	FIDR2	FIDR1	FIDR0
RW	RW	RW	RW	RW	RW	RW	RW

Initial value : 00H

FIDR[7:0] Flash Identification

Others No identification value

10100101 Identification value for a flash mode

(These bits are automatically cleared to logic '00H' immediately after one time operation)

FMCR (Flash Mode Control Register) : FEH

7	6	5	4	3	2	1	0
FMBUSY	–	–	–	–	FMCR2	FMCR1	FMCR0
R	–	–	–	–	RW	RW	RW

Initial value : 00H

FMBUSY Flash Mode Busy Bit. This bit will be used for only debugger.

0 No effect when "1" is written

1 Busy

FMCR[2:0] Flash Mode Control Bits. During a flash mode operation, the CPU is hold and the global interrupt is on disable state regardless of the IE.7 (EA) bit.

FMCR2 FM CR1 FMCR0 Description

0 0 1 Select flash page buffer reset mode and start regardless of the FIDR value (Clear all 64bytes to '0')

0 1 0 Select flash sector erase mode and start operation when the FIDR="10100101b'

0 1 1 Select flash sector write mode and start operation when the FIDR="10100101b'

1 0 0 Select flash sector hard lock and start operation when the FIDR="10100101b'

Others Values: No operation

(These bits are automatically cleared to logic '00H' immediately after one time operation)

15.1.6 Serial In-System Program (ISP) Mode

Serial in-system program uses the interface of debugger which uses two wires. Refer to chapter 14 in details about debugger

15.1.7 Protection Area (User program mode)

Z51F3220 can program its own flash memory (protection area). The protection area can not be erased or programmed. The protection areas are available only when the PAEN bit is cleared to '0', that is, enable protection area at the configure option 2 if it is needed. If the protection area isn't enabled (PAEN = '1'), this area can be used as a normal program memory.

The size of protection area can be varied by setting of configure option 2.

Table 15-2 Protection Area size

Protection Area Size Select		Size of Protection Area	Address of Protection Area
PASS1	PASS0		
0 0 3.		8k Bytes	0100H – 0FFFH
0 1 1.		7k Bytes	0100H – 07FFH
1 0	7	68 Bytes	0100H – 03FFH
1 1	2	56 Bytes	0100H – 01FFH

NOTE) Refer to chapter 16 in configure option control.

15.1.8 Erase Mode

The sector erase program procedure in user program mode

1. Page buffer clear (FMCR=0x01)
2. Write '0' to page buffer
3. Set flash sector address register (FSADRH/FSADRM/FSADRL).
4. Set flash identification register (FIDR).
5. Set flash mode control register (FMCR).
6. Erase verify

Program Tip – sector erase

```

                MOV    FMCR,#0x01          ;page buffer clear

NOP     ;Dummy instruction, This instruction must be needed.

```

16. Configure Option

16.1 Configure Option Control

The data for configure option should be written in the configure option area (003EH – 003FH) by programmer (Writer tools).

CONFIGURE OPTION 1 : ROM Address 003FH

7	6	5	4	3	2	1	0
R_P	HL	–	–	–	–	–	RSTS

Initial value : 00H

R_P	Read Protection
0	Disable "Read protection"
1	Enable "Read protection"
HL	Hard-Lock
0	Disable "Hard-lock"
1	Enable "Hard-lock"
RSTS	RESETB Select
0	P55 port
1	RESETB port with a pull-up resistor

CONFIGURE OPTION 2: ROM Address 003EH

7	6	5	4	3	2	1	0
–	–	–	–	–	PAEN	PASS1	PASS0

Initial value : 00H

PAEN	Protection Area Enable/Disable	
0	Disable Protection (Erasable by instruction)	
1	Enable Protection (Not erasable by instruction)	
PASS [1:0]	Protection Area Size Select	
PASS1	PASS0	Description
0	0	3.8k Bytes (Address 0100H – 0FFFH)
0	1	1.7k Bytes (Address 0100H – 07FFH)
1	0	768 Bytes (Address 0100H – 03FFH)
1	1	256 Bytes (Address 0100H – 01FFH)

17. APPENDIX

A. Instruction Table

Instructions are either 1, 2 or 3 bytes long as listed in the 'Bytes' column below.

Each instruction takes either 1, 2 or 4 machine cycles to execute as listed in the following table. 1 machine cycle comprises 2 system clock cycles.

ARITHMETIC				
Mnemonic	Description	Bytes	Cycles	Hex code
ADD A,Rn	Add register to A	1 1		28-2F
ADD A,dir	Add direct byte to A	2	1	25
ADD A,@Ri	Add indirect memory to A	1	1	26-27
ADD A,#data	Add immediate to A	2	1	24
ADDC A,Rn	Add register to A with carry	1	1	38-3F
ADDC A,dir	Add direct byte to A with carry	2	1	35
ADDC A,@Ri	Add indirect memory to A with carry	1	1	36-37
ADDC A,#data	Add immediate to A with carry	2	1	34
SUBB A,Rn	Subtract register from A with borrow	1	1	98-9F
SUBB A,dir	Subtract direct byte from A with borrow	2	1	95
SUBB A,@Ri	Subtract indirect memory from A with borrow	1	1	96-97
SUBB A,#data	Subtract immediate from A with borrow	2	1	94
INC A	Increment A	1	1	04
INC Rn	Increment register	1	1	08-0F
INC dir	Increment direct byte	2	1	05
INC @Ri	Increment indirect memory	1	1	06-07
DEC A	Decrement A	1	1	14
DEC Rn	Decrement register	1	1	18-1F
DEC dir	Decrement direct byte	2	1	15
DEC @Ri	Decrement indirect memory	1	1	16-17
INC DPTR	Increment data pointer	1	2	A3
MUL AB	Multiply A by B	1	4	A4
DIV AB	Divide A by B	1	4	84
DA A	Decimal Adjust A	1	1	D4

LOGICAL				
Mnemonic	Description	Bytes	Cycles	Hex code
ANL A,Rn	AND register to A	1 1		58-5F
ANL A,dir	AND direct byte to A	2	1	55
ANL A,@Ri	AND indirect memory to A	1	1	56-57
ANL A,#data	AND immediate to A	2	1	54
ANL dir,A	AND A to direct byte	2	1	52
ANL dir,#data	AND immediate to direct byte	3	2	53
ORL A,Rn	OR register to A	1	1	48-4F
ORL A,dir	OR direct byte to A	2	1	45
ORL A,@Ri	OR indirect memory to A	1	1	46-47
ORL A,#data	OR immediate to A	2	1	44
ORL dir,A	OR A to direct byte	2	1	42
ORL dir,#data	OR immediate to direct byte	3	2	43
XRL A,Rn	Exclusive-OR register to A	1	1	68-6F
XRL A,dir	Exclusive-OR direct byte to A	2	1	65
XRL A,@Ri	Exclusive-OR indirect memory to A	1	1	66-67

XRL A,#data	Exclusive-OR immediate to A	2	1	64
XRL dir,A	Exclusive-OR A to direct byte	2	1	62
XRL dir,#data	Exclusive-OR immediate to direct byte	3	2	63
CLR A	Clear A	1	1	E4
CPL A	Complement A	1	1	F4
SWAP A	Swap Nibbles of A	1	1	C4
RL A	Rotate A left	1	1	23
RLC A	Rotate A left through carry	1	1	33
RR A	Rotate A right	1	1	03
RRC A	Rotate A right through carry	1	1	13

DATA TRANSFER				
Mnemonic	Description	Bytes	Cycles	Hex code
MOV A,Rn	Move register to A	1	1	E8-EF
MOV A,dir	Move direct byte to A	2	1	E5
MOV A,@Ri	Move indirect memory to A	1	1	E6-E7
MOV A,#data	Move immediate to A	2	1	74
MOV Rn,A	Move A to register	1	1	F8-FF
MOV Rn,dir	Move direct byte to register	2	2	A8-AF
MOV Rn,#data	Move immediate to register	2	1	78-7F
MOV dir,A	Move A to direct byte	2	1	F5
MOV dir,Rn	Move register to direct byte	2	2	88-8F
MOV dir,dir	Move direct byte to direct byte	3	2	85
MOV dir,@Ri	Move indirect memory to direct byte	2	2	86-87
MOV dir,#data	Move immediate to direct byte	3	2	75
MOV @Ri,A	Move A to indirect memory	1	1	F6-F7
MOV @Ri,dir	Move direct byte to indirect memory	2	2	A6-A7
MOV @Ri,#data	Move immediate to indirect memory	2	1	76-77
MOV DPTR,#data	Move immediate to data pointer	3	2	90
MOVC A,@A+DPTR	Move code byte relative DPTR to A	1	2	93
MOVC A,@A+PC	Move code byte relative PC to A	1	2	83
MOVX A,@Ri	Move external data(A8) to A	1	2	E2-E3
MOVX A,@DPTR	Move external data(A16) to A	1	2	E0
MOVX @Ri,A	Move A to external data(A8)	1	2	F2-F3
MOVX @DPTR,A	Move A to external data(A16)	1	2	F0
PUSH dir	Push direct byte onto stack	2	2	C0
POP dir	Pop direct byte from stack	2	2	D0
XCH A,Rn	Exchange A and register	1	1	C8-CF
XCH A,dir	Exchange A and direct byte	2	1	C5
XCH A,@Ri	Exchange A and indirect memory	1	1	C6-C7
XCHD A,@Ri	Exchange A and indirect memory nibble	1	1	D6-D7

BOOLEAN				
Mnemonic	Description	Bytes	Cycles	Hex code
CLR C	Clear carry	1	1	C3
CLR bit	Clear direct bit	2	1	C2
SETB C	Set carry	1	1	D3
SETB bit	Set direct bit	2	1	D2
CPL C	Complement carry	1	1	B3
CPL bit	Complement direct bit	2	1	B2
ANL C,bit	AND direct bit to carry	2	2	82
ANL C,/bit	AND direct bit inverse to carry	2	2	B0

ORL C,bit	OR direct bit to carry	2	2	72
ORL C,/bit	OR direct bit inverse to carry	2	2	A0
MOV C,bit	Move direct bit to carry	2	1	A2
MOV bit,C	Move carry to direct bit	2	2	92

BRANCHING				
Mnemonic	Description	Bytes	Cycles	Hex code
ACALL addr 11	Absolute jump to subroutine	2 2		11→F1
LCALL addr 16	Long jump to subroutine	3	2	12
RET Return	from subroutine	1	2	22
RETI Return	from interrupt	1	2	32
AJMP addr 11	Absolute jump unconditional	2	2	01→E1
LJMP addr 16	Long jump unconditional	3	2	02
SJMP rel	Short jump (relative address)	2	2	80
JC rel	Jump on carry = 1	2	2	40
JNC rel	Jump on carry = 0	2	2	50
JB bit,rel	Jump on direct bit = 1	3	2	20
JNB bit,rel	Jump on direct bit = 0	3	2	30
JBC bit,rel	Jump on direct bit = 1 and clear	3	2	10
JMP @A+DPTR	Jump indirect relative DPTR	1	2	73
JZ rel	Jump on accumulator = 0	2	2	60
JNZ rel	Jump on accumulator ≠ 0	2	2	70
CJNE A,dir,rel	Compare A,direct jne relative	3	2	B5
CJNE A,#d,rel	Compare A,immediate jne relative	3	2	B4
CJNE Rn,#d,rel	Compare register, immediate jne relative	3	2	B8-BF
CJNE @Ri,#d,rel	Compare indirect, immediate jne relative	3	2	B6-B7
DJNZ Rn,rel	Decrement register, jnz relative	3	2	D8-DF
DJNZ dir,rel	Decrement direct byte, jnz relative	3	2	D5

MISCELLANEOUS				
Mnemonic	Description	Bytes	Cycles	Hex code
NOP No	operation	1 1		00

ADDITIONAL INSTRUCTIONS (selected through EO[7:4])				
Mnemonic	Description	Bytes	Cycles	Hex code
MOVC @(DPTR++),A	M8051W/M8051EW-specific instruction supporting software download into program memory	1 2		A5
TRAP So	ftware break command	1 1		A5

In the above table, an entry such as E8-EF indicates a continuous block of hex opcodes used for 8 different registers, the register numbers of which are defined by the lowest three bits of the corresponding code. Non-continuous blocks of codes, shown as 11→F1 (for example), are used for absolute jumps and calls, with the top 3 bits of the code being used to store the top three bits of the destination address.

The CJNE instructions use the abbreviation #d for immediate data; other instructions use #data.

B. Instructions on how to use the input port.

- Error occur status
 - Using compare jump instructions with input port, it could cause error due to the timing conflict inside the MCU.
 - Compare jump Instructions which cause potential error used with input port condition:

```
JB    bit, rel    ; jump on direct bit=1
JNB   bit, rel    ; jump on direct bit=0
JBC   bit, rel    ; jump on direct bit=1 and clear
CJNE  A, dir, rel ; compare A, direct jne relative
DJNZ  dir, rel    ; decrement direct byte, jnz relative
```

- It is only related with Input port. Internal parameters, SFRs and output bit ports don't cause any error by using compare jump instructions.
- If input signal is fixed, there is no error in using compare jump instructions.

- Error status example

```
while(1){
  if (P00==1){ P10=1; }
  else { P10=0; }
  P11^=1;
}
```

```
zzz:  JNB    080.0, xxx ; it possible to be error
      SETB   088.0
      SJMP   yyy
xxx:  CLR    088.0
yyy:  MOV     C,088.1
      CPL    C
      MOV    088.1,C
      SJMP   zzz
```

```
unsigned char ret_bit_err(void)
{
  return !P00;
}
```

```
MOV    R7, #000
JB      080.0, xxx ; it possible to be error
MOV    R7, #001
xxx:  RET
```

- Preventative measures (2 cases)
 - Do not use input bit port for bit operation but for byte operation. Using byte operation instead of bit operation will not cause any error in using compare jump instructions for input port.

```
while(1){
  if ((P0&0x01)==0x01){ P10=1; }
  else { P10=0; }
  P11^=1;
}
```

```
zzz:  MOV     A, 080      ; read as byte
      JNB    0E0.0, xxx  ; compare
      SETB   088.0
      SJMP   yyy
xxx:  CLR    088.0
yyy:  MOV     C,088.1
      CPL    C
      MOV    088.1,C
      SJMP   zzz
```

- If you use input bit port for compare jump instruction, you have to copy the input port as internal parameter or carry bit and then use compare jump instruction.

```
bit tt;
while(1){
    tt=P00;
    if (tt==0){ P10=1;}
    else {P10=0;}
    P11^=1;
}
```

```
zzz:  MOV    C,080.0    ; input port use internal parameter
      MOV    020.0, C    ; move
      JB     020.0, xxx   ; compare
      SETB   088.0
      SJMP   yyy
xxx:   CLR    088.0
yyy:   MOV    C,088.1
      CPL    C
      MOV    088.1,C
      SJMP   zzz
```
