

To all our customers

---

## **Regarding the change of names mentioned in the document, such as Hitachi Electric and Hitachi XX, to Renesas Technology Corp.**

---

The semiconductor operations of Mitsubishi Electric and Hitachi were transferred to Renesas Technology Corporation on April 1st 2003. These operations include microcomputer, logic, analog and discrete devices, and memory chips other than DRAMs (flash memory, SRAMs etc.) Accordingly, although Hitachi, Hitachi, Ltd., Hitachi Semiconductors, and other Hitachi brand names are mentioned in the document, these names have in fact all been changed to Renesas Technology Corp. Thank you for your understanding. Except for our corporate trademark, logo and corporate statement, no changes whatsoever have been made to the contents of the document, and these changes do not constitute any alteration to the contents of the document itself.

## Cautions

Keep safety first in your circuit designs!

1. Renesas Technology Corporation puts the maximum effort into making semiconductor products better and more reliable, but there is always the possibility that trouble may occur with them. Trouble with semiconductors may lead to personal injury, fire or property damage.

Remember to give due consideration to safety when making your circuit designs, with appropriate measures such as (i) placement of substitutive, auxiliary circuits, (ii) use of nonflammable material or (iii) prevention against any malfunction or mishap.

Notes regarding these materials

1. These materials are intended as a reference to assist our customers in the selection of the Renesas Technology Corporation product best suited to the customer's application; they do not convey any license under any intellectual property rights, or any other rights, belonging to Renesas Technology Corporation or a third party.
2. Renesas Technology Corporation assumes no responsibility for any damage, or infringement of any third-party's rights, originating in the use of any product data, diagrams, charts, programs, algorithms, or circuit application examples contained in these materials.

3. All information contained in these materials, including product data, diagrams, charts, programs and algorithms represents information on products at the time of publication of these materials, and are subject to change by Renesas Technology Corporation without notice due to product improvements or other reasons. It is therefore recommended that customers contact Renesas Technology Corporation or an authorized Renesas Technology Corporation product distributor for the latest product information before purchasing a product listed herein.

The information described here may contain technical inaccuracies or typographical errors.

Renesas Technology Corporation assumes no responsibility for any damage, liability, or other loss rising from these inaccuracies or errors.

Please also pay attention to information published by Renesas Technology Corporation by various means, including the Renesas Technology Corporation Semiconductor home page (<http://www.renesas.com>).

4. When using any or all of the information contained in these materials, including product data, diagrams, charts, programs, and algorithms, please be sure to evaluate all information as a total system before making a final decision on the applicability of the information and products. Renesas Technology Corporation assumes no responsibility for any damage, liability or other loss resulting from the information contained herein.
5. Renesas Technology Corporation semiconductors are not designed or manufactured for use in a device or system that is used under circumstances in which human life is potentially at stake. Please contact Renesas Technology Corporation or an authorized Renesas Technology Corporation product distributor when considering the use of a product contained herein for any specific purposes, such as apparatus or systems for transportation, vehicular, medical, aerospace, nuclear, or undersea repeater use.
6. The prior written approval of Renesas Technology Corporation is necessary to reprint or reproduce in whole or in part these materials.
7. If these products or technologies are subject to the Japanese export control restrictions, they must be exported under a license from the Japanese government and cannot be imported into a country other than the approved destination.  
Any diversion or reexport contrary to the export control laws and regulations of Japan and/or the country of destination is prohibited.
8. Please contact Renesas Technology Corporation for further details on these materials or the products contained therein.

The revision list can be viewed directly by clicking the title page.

The revision list summarizes the locations of revisions and additions. Details should always be checked by referring to the relevant text.

## Cautions

1. Hitachi neither warrants nor grants licenses of any rights of Hitachi's or any third party's patent, copyright, trademark, or other intellectual property rights for information contained in this document. Hitachi bears no responsibility for problems that may arise with third party's rights, including intellectual property rights, in connection with use of the information contained in this document.
2. Products and product specifications may be subject to change without notice. Confirm that you have received the latest product standards or specifications before final design, purchase or use.
3. Hitachi makes every attempt to ensure that its products are of high quality and reliability. However, contact Hitachi's sales office before using the product in an application that demands especially high quality and reliability or where its failure or malfunction may directly threaten human life or cause risk of bodily injury, such as aerospace, aeronautics, nuclear power, combustion control, transportation, traffic, safety equipment or medical equipment for life support.
4. Design your application so that the product is used within the ranges guaranteed by Hitachi particularly for maximum rating, operating supply voltage range, heat radiation characteristics, installation conditions and other characteristics. Hitachi bears no responsibility for failure or damage when used beyond the guaranteed ranges. Even within the guaranteed ranges, consider normally foreseeable failure rates or failure modes in semiconductor devices and employ systemic measures such as fail-safes, so that the equipment incorporating Hitachi product does not cause bodily injury, fire or other consequential damage due to operation of the Hitachi product.
5. This product is not designed to be radiation resistant.
6. No one is permitted to reproduce or duplicate, in any form, the whole or part of this document without written approval from Hitachi.
7. Contact Hitachi's sales office for any questions regarding this document or Hitachi semiconductor products.

## General Precautions on Handling of Product

### 1. Treatment of NC Pins

**Note:** Do not connect anything to the NC pins.

The NC (not connected) pins are either not connected to any of the internal circuitry or are they are used as test pins or to reduce noise. If something is connected to the NC pins, the operation of the LSI is not guaranteed.

### 2. Treatment of Unused Input Pins

**Note:** Fix all unused input pins to high or low level.

Generally, the input pins of CMOS products are high-impedance input pins. If unused pins are in their open states, intermediate levels are induced by noise in the vicinity, a pass-through current flows internally, and a malfunction may occur.

### 3. Processing before Initialization

**Note:** When power is first supplied, the product's state is undefined.

The states of internal circuits are undefined until full power is supplied throughout the chip and a low level is input on the reset pin. During the period where the states are undefined, the register settings and the output state of each pin are also undefined. Design your system so that it does not malfunction because of processing while it is in this undefined state. For those products which have a reset function, reset the LSI immediately after the power supply has been turned on.

### 4. Prohibition of Access to Undefined or Reserved Addresses

**Note:** Access to undefined or reserved addresses is prohibited.

The undefined or reserved addresses may be used to expand functions, or test registers may have been allocated to these addresses. Do not access these registers; the system's operation is not guaranteed if they are accessed.

# Configuration of This Manual

This manual comprises the following items:

1. General Precautions on Handling of Product
2. Configuration of This Manual
3. Preface
4. Contents
5. Overview
6. Description of Functional Modules

- CPU and System-Control Modules

- On-Chip Peripheral Modules

The configuration of the functional description of each module differs according to the module. However, the generic style includes the following items:

- i) Feature
- ii) Input/Output Pin
- iii) Register Description
- iv) Operation
- v) Usage Note

When designing an application system that includes this LSI, take notes into account. Each section includes notes in relation to the descriptions given, and usage notes are given, as required, as the final part of each section.

7. List of Registers
8. Electrical Characteristics
9. Appendix
10. Main Revisions and Additions in this Edition (only for revised versions)

The list of revisions is a summary of points that have been revised or added to earlier versions. This does not include all of the revised contents. For details, see the actual locations in this manual.

11. Index

# Preface

The SH7706 RISC (Reduced Instruction Set Computer) microcomputer includes a Hitachi-original RISC CPU as its core, and the peripheral functions required to configure a system.

**Target Users:** This manual was written for users who will be using this LSI in the design of application systems. Users of this manual are expected to understand the fundamentals of electrical circuits, logical circuits, and microcomputers.

**Objective:** This manual was written to explain the hardware functions and electrical characteristics of this LSI to the above users.  
Refer to the SH-3/SH-3E/SH3-DSP Programming Manual for a detailed description of the instruction set.

Notes on reading this manual:

- Product names  
The following products are covered in this manual.

## Product Classifications and Abbreviations

| Basic Classification           | Product Code    |
|--------------------------------|-----------------|
| SH7706 (176-pin plastic LQFP)  | HD6417706F133   |
| SH7706 (208-pin plastic TFBGA) | HD6417706BP133V |

- In order to understand the overall functions of the chip

Read the manual according to the contents. This manual can be roughly categorized into parts on the CPU, system control functions, peripheral functions and electrical characteristics.

- In order to understand the details of the CPU's functions

Read the SH-3/SH-3E/SH3-DSP Programming Manual.

- Rules: Register name: The following notation is used for cases when the same or a similar function, e.g. serial communication, is implemented on more than one channel:  
XXX\_N (XXX is the register name and N is the channel number)
- Bit order: The MSB (most significant bit) is on the left and the LSB (least significant bit) is on the right.
- Number notation: Binary is B'xxxx, hexadecimal is H'xxxx, decimal is xxxx.
- Signal notation: An overbar is added to a low-active signal:  $\overline{\text{xxxx}}$

Related Manuals: The latest versions of all related manuals are available from our web site. Please ensure you have the latest versions of all documents you require.

# Section 1 Overview

The SH7706 is a RISC microprocessor that integrates a Hitachi-original RISC-type SuperH™ architecture SH-3 CPU as its core that has peripheral functions required for system configuration. The CPU of this LSI has upper compatibility with the SH-1 and SH-2 at object code level. This LSI incorporates a memory management unit (MMU) that has a 128-entry 4-way set associative translation lookaside buffer (TLB).

The LSI incorporates the following peripheral functions: an on-chip direct memory access controller (DMAC) that enables high-speed data transfer and a bus state controller (BSC) that enables direct connection to different types of memory. The LSI also incorporates a serial communication interface, an A/D converter, a D/A converter, a timer, and a realtime clock that enable system configuration at low cost.

A built-in power management function enables dynamic control of power consumption. Thus, this LSI is optimum for portable electronic devices such as PDAs that require both high performance and low power.

The SH7706 incorporates a Hitachi user debug interface (H-UDI) and an advanced user debugger (AUD) to support emulator functions such as E10A. This LSI also incorporates a user break controller (UBC) for self debugging.

## 1.1 Feature

- Original Hitachi SuperH architecture
- Object code level compatible with SH-1, SH-2 and SH-3
- 32-bit RISC-type instruction set
  - Instruction length: 16-bit fixed length
  - Improved code efficiency
  - Load-store architecture
  - Delayed branch instructions
  - Instruction set oriented for C language
- Five-stage pipeline
- Instruction execution time: one instruction/cycle for basic instructions
- General-register: Sixteen 32-bit general registers
- Control-register: Eight 32-bit control registers
- System-register: Four 32-bit system registers
- 32-bit internal data bus
- Logical address space: 4 Gbytes
- Space identifier ASID: 8 bits, 256 logical address space

- Abundant Peripheral Functions
  - Memory Management Unit (MMU)
  - User Break Controller (UBC)
  - Bus state Controller (BSC)
  - Direct Memory Access Controller (DMAC)
  - Clock Pulse Generator (CPG)
  - Watchdog Timer (WDT)
  - Timer Unit (TMU)
  - Realtime Clock (RTC)
  - Serial Communication Interface (SCI)
  - Smartcard Interface
  - Serial Communication Interface with FIFO (SCIF)
  - 10-bitits A/D converter (ADC)
  - 8-bitit D/A converter (DAC)
  - Hitachi User Debugging Interface (H-UDI)
  - Advanced User Debugger (AUD)

## 1.2 Block Diagram

### Legend

## 1.4 Pin Function

### Number of Pins

| FP-176C | TBP-208AV | Pin Name                    | I/O | Description                        |
|---------|-----------|-----------------------------|-----|------------------------------------|
| 1       | C3        | $V_{CC}$ -RTC* <sup>1</sup> | —   | RTC power supply (1.9 V)           |
| 2       | C2        | XTAL2                       | O   | On-chip RTC crystal oscillator pin |
| 3       | C1        | EXTAL2                      | I   | On-chip RTC crystal oscillator pin |
| 4       | D3        | $V_{SS}$ -RTC* <sup>1</sup> | —   | RTC power supply (0 V)             |
| 5       | F4        | D31/PTB[7]                  | I/O | Data bus / input/output port B     |
| 6       | F3        | D30/PTB[6]                  | I/O | Data bus / input/output port B     |
| 7       | F2        | D29/PTB[5]                  | I/O | Data bus / input/output port B     |
| 8       | F1        | D28/PTB[4]                  | I/O | Data bus / input/output port B     |
| 9       | G4        | D27/PTB[3]                  | I/O | Data bus / input/output port B     |
| 10      | G3        | D26/PTB[2]                  | I/O | Data bus / input/output port B     |
| 11      | G2        | $V_{SS}$ Q                  | —   | Input/output power supply (0 V)    |
| 12      | G1        | D25/PTB[1]                  | I/O | Data bus / input/output port B     |
| 13      | H4        | $V_{CC}$ Q                  | —   | Input/output power supply (3.3 V)  |
| 14      | H3        | D24/PTB[0]                  | I/O | Data bus / input/output port B     |
| 15      | H2        | D23/PTA[7]                  | I/O | Data bus / input/output port A     |
| 16      | H1        | D22/PTA[6]                  | I/O | Data bus / input/output port A     |
| 17      | J4        | D21/PTA[5]                  | I/O | Data bus / input/output port A     |
| 18      | J2        | D20/PTA[4]                  | I/O | Data bus / input/output port A     |
| 19      | J1        | $V_{SS}$                    | —   | Internal power supply (0 V)        |
| 20      | J3        | D19/PTA[3]                  | I/O | Data bus / input/output port A     |
| 21      | K1        | $V_{CC}$                    | —   | Internal power supply (1.9 V)      |
| 22      | K2        | D18/PTA[2]                  | I/O | Data bus / input/output port A     |
| 23      | K3        | D17/PTA[1]                  | I/O | Data bus / input/output port A     |
| 24      | K4        | D16/PTA[0]                  | I/O | Data bus / input/output port A     |
| 25      | L1        | $V_{SS}$ Q                  | —   | Input/output power supply (0 V)    |
| 26      | L2        | D15                         | I/O | Data bus                           |
| 27      | L3        | $V_{CC}$ Q                  | —   | Input/output power supply (3.3 V)  |
| 28      | L4        | D14                         | I/O | Data bus                           |
| 29      | M1        | D13                         | I/O | Data bus                           |

## Number of Pins

| FP-176C | TBP-208AV | Pin Name  | I/O | Description                       |
|---------|-----------|-----------|-----|-----------------------------------|
| 30      | M2        | D12       | I/O | Data bus                          |
| 31      | M3        | D11       | I/O | Data bus                          |
| 32      | M4        | D10       | I/O | Data bus                          |
| 33      | N1        | D9        | I/O | Data bus                          |
| 34      | N2        | D8        | I/O | Data bus                          |
| 35      | N3        | D7        | I/O | Data bus                          |
| 36      | N4        | D6        | I/O | Data bus                          |
| 37      | P1        | $V_{SS}Q$ | —   | Input/output power supply (0 V)   |
| 38      | P2        | D5        | I/O | Data bus                          |
| 39      | P3        | $V_{CC}Q$ | —   | Input/output power supply (3.3 V) |
| 40      | R1        | D4        | I/O | Data bus                          |
| 41      | R2        | D3        | I/O | Data bus                          |

| 155     | A10       | IRQ4/PTH[4]       | I / I/O     | External interrupt request / input/output port H              |

## Number of Pins

| FP-176C | TBP-208AV | Pin Name                  | I/O       | Description                                               |
|---------|-----------|---------------------------|-----------|-----------------------------------------------------------|
| 156     | D9        | $V_{SS}Q$                 | —         | Input/output power supply (0 V)                           |
| 157     | B9        | NMI                       | I         | Nonmaskable interrupt request                             |
| 158     | A9        | $V_{CC}Q$                 | —         | Input/output power supply (3.3 V)                         |
| 159     | C9        | AUDCK/PTG[4]              | I         | AUD clock / input port G                                  |
| 160     | A8        | $\overline{DREQ0}/PTH[5]$ | I / I/O   | DMA request / input/output port H                         |
| 161     | B8        | $\overline{DREQ1}/PTH[6]$ | I / I/O   | DMA request / input/output port H                         |
| 162     | C8        | $\overline{ADTRG}/PTG[5]$ | I         | Analog trigger / input port G                             |
| 163     | D8        | MD0                       | I         | Clock mode setting                                        |
| 164     | B7        | MD2                       | I         | Clock mode setting                                        |
| 165     | A6        | $\overline{RESETP}$       | I         | Power-on reset request                                    |
| 166     | B6        | CA                        | I         | Chip activate / hardware standby request                  |
| 167     | C6        | MD3                       | I         | Area 0 bus width setting                                  |
| 168     | D6        | MD4                       | I         | Area 0 bus width setting                                  |
| 169     | A5        | MD5                       | I         | Endian setting                                            |
| 170     | B5        | $AV_{SS}$                 | —         | Analog power supply (0 V)                                 |
| 171     | C5        | AN[0]/PTJ[0]              | I         | A/D converter input / input port J                        |
| 172     | D5        | AN[1]/PTJ[1]              | I         | A/D converter input / input port J                        |
| 173     | A4        | AN2[2]/DA[1]/PTJ[2]       | I / O / I | A/D converter input / D/A converter output / input port J |
| 174     | B4        | AN3[3]/DA[0]/PTJ[3]       | I / O / I | A/D converter input / D/A converter output / input port J |
| 175     | B3        | $AV_{CC}$                 | —         | Analog power supply (3.3 V)                               |
| 176     | B2        | $AV_{SS}$                 | —         | Analog power supply (0 V)                                 |

Notes: \*1. Must be connected to the power supply even when the RTC is not used.

\*2. Must be connected to the power supply even when the on-chip PLL circuits are not used (except in hardware standby mode).

\*3. Must be high level when the user system is used independently without using the emulator or H-UDI. When this pin goes low or is open, the RESETP pin may be masked. (See section 21, Hitachi User-Debugging Interface (H-UDI).)

1. Except in hardware standby mode, all  $V_{CC}/V_{SS}$  pins must be connected to the system power supply. (Supply power constantly.) In hardware standby mode, power must be supplied at least to  $V_{CC-RTC}$  and  $V_{SS-RTC}$ . If power is not supplied to  $V_{CC}$  and  $V_{SS}$  pins other than  $V_{CC-RTC}$  and  $V_{SS-RTC}$ , hold the CA pin low.
2. In the TBP-208A package, the A1, A2, A3, A7, A12, B1, C4, C7, D1, D2, D4, D7, D14, D15, E1, E2, E3, E4, F14, F17, G17, H14, H15, K14, P14, R10, T13, T15, T16, U11, U15, and U16 pins must be connected to  $V_{SS}$ .

## 2.1 Register Description

### 2.1.1 Privileged Mode and Banks

**Processor Modes:** There are two processor modes: user mode and privileged mode. The SH7706 normally operates in user mode, and enters privileged mode when an exception occurs or an interrupt is accepted. There are three kinds of registers—general registers, system registers, and control registers—and the registers that can be accessed differ in the two processor modes.

**General Registers:** There are 16 general registers, designated R0 to R15. General registers R0 to R7 are banked registers which are switched by a processor mode change. In privileged mode, the register bank bit (RB) in the status register (SR) defines which banked register set is accessed as general registers, and which set is accessed only through the load control register (LDC) and store control register (STC) instructions.

When the RB bit is 1, BANK1 general registers R0\_BANK1–R7\_BANK1 and non-banked general registers R8–R15 function as the general register set, with BANK0 general registers R0\_BANK0–R7\_BANK0 accessed only by the LDC/STC instructions.

When the RB bit is 0, BANK0 general registers R0\_BANK0–R7\_BANK0 and nonbanked general registers R8–R15 function as the general register set, with BANK1 general registers R0\_BANK1–R7\_BANK1 accessed only by the LDC/STC instructions. In user mode, the 16 registers comprising bank 0 general registers R0\_BANK0–R7\_BANK0 and non-banked registers R8–R15 can be accessed as general registers R0–R15, and bank 1 general registers R0\_BANK1–R7\_BANK1 cannot be accessed.

**Control Registers:** Control registers comprise the global base register (GBR) and status register (SR) which can be accessed in both processor modes, and the saved status register (SSR), saved program counter (SPC), and vector base register (VBR) which can only be accessed in privileged mode. Some bits of the status register (such as the RB bit) can only be accessed in privileged mode.

**System Registers:** System registers comprise the multiply and accumulate registers (MACL/MACH), the procedure register (PR), and the program counter (PC). Access to these registers does not depend on the processor mode.

The register configuration in each mode is shown in figures 2.1.

Switching between user mode and privileged mode is controlled by the processor mode bit (MD) in the status register.

|                                         |   |                                         |   |                                         |   |
|-----------------------------------------|---|-----------------------------------------|---|-----------------------------------------|---|

a. User mode register configuration

b. Privileged mode register configuration (RB = 1)

c. Privileged mode register configuration (RB = 0)

- Notes: 1. R0 functions as an index register in the indexed register-indirect addressing mode and indexed GBR-indirect addressing mode.
2. Banked register
3. Banked register  
When the RB bit of the SR register is 1, the register can be accessed for general use. When the RB bit is 0, it can only be accessed with the LDC/STC instruction.
4. Banked register  
When the RB bit of the SR register is 0, the register can be accessed for general use. When the RB bit is 1, it can only be accessed with the LDC/STC instruction.

**Figure 2.1 Register Configuration**

Register values after a reset are shown in table 2.1.

**Table 2.1 Initial Register Values**

| Type              | Registers      | Initial Value*                                                                              |
|-------------------|----------------|---------------------------------------------------------------------------------------------|

Note: \* Initial value is set at power-on-reset or manual-reset.

## 2.1.2 General Registers

There are 16 general registers, designated R0 to R15. General registers R0 to R7 are banked registers, with a different R0–R7 register bank (R0\_BANK0–R7\_BANK0 or R0\_BANK1–R7\_BANK1) being accessed according to the processor mode. For details, see figure 2.1.

The general register configuration is shown in figure 2.2.

**Figure 2.2 General Registers**

### 2.1.3 System Registers

System registers can be accessed by the LDS and STS instructions. When an exception occurs, the contents of the program counter (PC) are saved in the saved program counter (SPC). The SPC contents are restored to the PC by the RTE instruction used at the end of the exception handling. There are three system registers, as follows.

- Multiply and accumulate register (MAC)
- Procedure register (PR)
- Program counter (PC)

The system register configuration is shown in figure 2.3.

**Figure 2.3 System Registers**

#### 1. Multiply and Accumulate Register (MAC)

Multiply and Accumulate register is consist of Higher part register (MACH) and Lower part register (MACL).

Store the results of multiply-and-accumulate operations.

Initialized to undefined by a reset.

#### 2. Procedure Register (PR)

Stores the return address for exiting a subroutine procedure.

Initialized to undefined by a reset.

#### 3. Program Counter (PC)

Indicates the address four addresses (two instructions) ahead of the currently executing instruction. Initialized to H'A0000000 by a reset.

### 2.1.4 Control Registers

Control registers can be accessed in privileged mode using the LDC and STC instructions. The GBR register can also be accessed in user mode. There are five control registers, as follows:

- Status register (SR)
- Saved status register (SSR)
- Saved program counter (SPC)
- Global base register (GBR)
- Vector base register (VBR)

The control register configuration is shown in figure 2.4.

**Figure 2.4 Control Registers**

- **Status Register (SR)**

The information of system status are set in this register.

| Bit      | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                                                                                                                                                                                                                     |

| 4   | I0       | 1             | R/W | I3–I0 do not change to the interrupt acceptance level when an interrupt is occurred.                                                                                                                                                                                                               |
| 3   | —        | 0             | R   | Reserved                                                                                                                                                                                                                                                                                           |
| 2   | —        | 0             | R   | These bits always read as 0, and the write value should always be 0.                                                                                                                                                                                                                               |
| 1   | S        | —             | R/W | S bit<br>Used by the MAC instruction.                                                                                                                                                                                                                                                              |
| 0   | T        | —             | R/W | T bit<br>Used by the MOV <sub>T</sub> , CMP/conned, TAS, TST, BT, BF, SETT, CLRT, and DT instructions to indicate true (1) or false (0).<br>Used by the ADDV/C, SUBV/C, DIV0U/S, DIV1, NEGC, SHAR/L, SHLR/L, ROTR/L, and ROTCR/L instructions to indicate a carry, borrow, overflow, or underflow. |

**Note:** The M, Q, S and T bits can be set or cleared by special instructions in user mode. Their values are undefined after a reset. All other bits can be read or written in privileged mode.

- Saved Status Register (SSR)**  
 Stores current SR value at time of exception to indicate processor status in return to instruction stream from exception handler.  
 Initialized to undefined by a reset.
- Saved Program Counter (SPC)**  
 Stores current PC value at time of exception to indicate return address at completion of exception handling.  
 Initialized to undefined by a reset.

- **Global Base Register (GBR)**  
Stores base address of GBR-indirect addressing mode. The GBR-indirect addressing mode is used for on-chip supporting module register area data transfers and logic operations.  
The GBR register can also be accessed in user mode.  
Initialized to undefined by a reset.
- **Vector Base Register (VBR)**  
Stores base address of exception handling vector area.  
Initialized to H'0000000 by a reset.

## 2.2 Data Formats

### 2.2.1 Data Format in Registers

Register operands are always longwords (32 bits). When a memory operand is only a byte (8 bits) or a word (16 bits), the sign is extended to the longword, and stores into the register.

### 2.2.2 Data Format in Memory

Memory data formats are classified into bytes, words, and longwords. Memory can be accessed in 8-bit byte, 16-bit word, or 32-bit longword form. A memory operand less than 32 bits in length is sign-extended before being stored in a register.

A word operand must be accessed starting from a word boundary (even address of a 2-byte unit: address 2n), and a longword operand starting from a longword boundary (even address of a 4-byte unit: address 4n). An address error will result if this rule is not observed. A byte operand can be accessed from any address.

Big-endian or little-endian byte order can be selected for the data format. The endian mode should be set with the MD5 external pin in a power-on reset. Big-endian mode is selected when the MD5 pin is low, and little-endian when high. The endian mode cannot be changed dynamically. Bit positions are numbered left to right from most-significant to least-significant. Thus, in a 32-bit longword, the leftmost bit, bit 31, is the most significant bit and the rightmost bit, bit 0, is the least significant bit.

The data format in memory is shown in figure 2.5.

**Figure 2.5 Data Format in Memory**

## 2.3 Instruction Features

### 2.3.1 Execution Environment

**Data Length:** The instruction set is implemented with fixed-length 16-bit wide instructions executed in a pipelined sequence with single-cycle execution for most instructions. All operations are executed in 32-bit longword units. Memory can be accessed in 8-bit byte, 16-bit word, or 32-bit longword units, with byte or word units sign-extended into 32-bit longwords. Literals are sign-extended in arithmetic operations (MOV, ADD, and CMP/EQ instructions) and zero-extended in logical operations (TST, AND, OR, and XOR instructions).

**Load/Store Architecture:** The load-store architecture is used, so basic operations are executed by the registers. Operations requiring memory access are executed in registers following register loading, except for bit-manipulation operations such as logical AND functions, which are executed directly in memory.

**Delayed Branching:** Unconditional branching is implemented as delayed branch operations. Pipeline disruptions due to branching are minimized by the execution of the instruction following the delayed branch instruction prior to branching. Conditional branch instructions are of two kinds, delayed and normal.

```
BRA      TRGET
ADD      R1, R0    ;ADD is executed prior to branching to TRGET
```

**T bit:** The T bit in the status register (SR) is used to indicate the result of compare operations, and is read as a TRUE/FALSE condition determining if a conditional branch is taken or not. To improve processing speed, the T bit logic state is modified only by specific operations. An example of how the T bit may be used in a sequence of operations is shown below.

|        |        |                                                |
|--------|--------|------------------------------------------------|
| ADD    | #1, R0 | ;T bit not modified by ADD operation           |
| CMP/EQ | R1, R0 | ;T bit set to 1 when R0 = 0                    |
| BT     | TRGET  | ;branch taken to TRGET when T bit = 1 (R0 = 0) |

**Literals:** Byte-length literals are inserted directly into the instruction code as immediate data. To maintain the 16-bit fixed-length instruction code, word or longword literals are stored in a table in main memory rather than inserted directly into the instruction code. The memory table is accessed by the MOV instruction using PC-relative addressing with displacement, as follows:

```
MOV.W    @(disp, PC), R0
```

**Absolute Addresses:** As with word and longword literals, absolute addresses must also be stored in a table in main memory. The value of the absolute address is transferred to a register and the operand access is specified by indexed register-indirect addressing, with the absolute address loaded (like word and longword immediate data) during instruction execution.

**16-Bit and 32-Bit Displacements:** In the same way, 16-bit and 32-bit displacements also must be stored in a table in main memory. Exactly like absolute addresses, the displacement value is transferred to a register and the operand access is specified by indexed register-indirect addressing, loading the displacement (like word and longword immediate data) during instruction execution.

### 2.3.2 Addressing Modes

Addressing modes and effective address calculation methods are shown in table 2.2.

**Table 2.2 Addressing Modes and Effective Addresses**

| Addressing Mode                       | Instruction Format | Effective Address Calculation Method                                                                                                                                                                                                                         | Calculation Formula                                                                                                                                     |
|---------------------------------------|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| Register direct                       | Rn                 | Effective address is register Rn. (Operand is register Rn contents.)                                                                                                                                                                                         | —                                                                                                                                                       |
| Register indirect                     | @Rn                | Effective address is register Rn contents.<br>                                                                                                                              | Rn                                                                                                                                                      |
| Register indirect with post-increment | @Rn+               | Effective address is register Rn contents. A constant is added to Rn after instruction execution: 1 for a byte operand, 2 for a word operand, 4 for a longword operand.<br> | Rn<br>After instruction execution<br>Byte: $Rn + 1 \rightarrow Rn$<br>Word: $Rn + 2 \rightarrow Rn$<br>Longword: $Rn + 4 \rightarrow Rn$                |
| Register indirect with pre-decrement  | @-Rn               | Effective address is register Rn contents, decremented by a constant beforehand: 1 for a byte operand, 2 for a word operand, 4 for a longword operand.<br>                 | Byte: $Rn - 1 \rightarrow Rn$<br>Word: $Rn - 2 \rightarrow Rn$<br>Longword: $Rn - 4 \rightarrow Rn$<br>(Instruction executed with Rn after calculation) |

| Addressing Mode                                                                     | Instruction Format | Effective Address Calculation Method                                                                                                                                                                | Calculation Formula                                                                  |
|-------------------------------------------------------------------------------------|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------|
| Register indirect with displacement                                                 | @(disp:4, Rn)      | Effective address is register Rn contents with 4-bit displacement disp added. After disp is zero-extended, it is multiplied by 1 (byte), 2 (word), or 4 (longword), according to the operand size.  | Byte: $Rn + disp$<br>Word: $Rn + disp \times 2$<br>Longword: $Rn + disp \times 4$    |

The PC and disp (sign-extended) inputs are connected to an adder (+). The output of the adder is the effective address, which is PC + disp × 2.</p>                                                                                                                                                                                                                                                                                               |                    |                                                                                                                                                                                                                                                      |                                                                            |

| Addressing Mode | Instruction Format | Effective Address Calculation Method                                                                                                                                                                                                                      | Calculation Formula |
|-----------------|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------|
| PC-relative     | Rn                 | Effective address is sum of register PC and Rn contents.<br> <pre> graph LR     PC[PC] --&gt; Adder((+))     R0[R0] --&gt; Adder     Adder --&gt; Result[PC + R0] </pre> | $PC + Rn$           |
| Immediate       | #imm:8             | 8-bit immediate data imm of TST, AND, OR, or XOR instruction is zero-extended.                                                                                                                                                                            | —                   |
|                 | #imm:8             | 8-bit immediate data imm of MOV, ADD, or CMP/EQ instruction is sign-extended.                                                                                                                                                                             | —                   |
|                 | #imm:8             | 8-bit immediate data imm of TRAPA instruction is zero-extended and multiplied by 4.                                                                                                                                                                       | —                   |

**Note:** For the addressing modes below that use a displacement (disp), the assembler descriptions in this manual show the value before scaling ( $\times 1$ ,  $\times 2$ , or  $\times 4$ ) is performed according to the operand size. This is done to clarify the operation of the IC. Refer to the relevant assembler notation rules for the actual assembler descriptions.

@ (disp:4, Rn) ; Register indirect with displacement

@ (disp:8, Rn) ; GBR indirect with displacement

@ (disp:8, PC) ; PC-relative with displacement

disp:8, disp:12; PC-relative

### 2.3.3 Instruction Formats

Table 2.3 explains the meaning of instruction formats and source and destination operands. The meaning of the operands depends on the operation code. The following symbols are used.

xxxx: Operation code  
 mmmm: Source register  
 nnnn: Destination register  
 iiii: Immediate data  
 dddd: Displacement

**Table 2.3 Instruction Formats**

| Instruction Format | Source Operand                              | Destination Operand                        | Instruction Example                              |
|--------------------|---------------------------------------------|--------------------------------------------|--------------------------------------------------|

Note: \* In a multiply-and-accumulate instruction, nnnn is the source register.

## 2.4 Instruction Set

### 2.4.1 Instruction Set Classified by Function

The SH7706 instruction set includes 68 basic instruction types, as listed in table 2.4.

**Table 2.4 Classification of Instructions**

| Classification        | Types | Operation Code | Function                                                                              | No. of Instructions |
|-----------------------|-------|----------------|---------------------------------------------------------------------------------------|---------------------|
| Data transfer         | 5     | MOV            | Data transfer                                                                         | 39                  |
|                       |       | MOVA           | Effective address transfer                                                            |                     |
|                       |       | MOVT           | T bit transfer                                                                        |                     |
|                       |       | SWAP           | Swap of upper and lower bytes                                                         |                     |
|                       |       | XTRCT          | Extraction of middle of linked registers                                              |                     |
| Arithmetic operations | 21    | ADD            | Binary addition                                                                       | 33                  |
|                       |       | ADDC           | Binary addition with carry                                                            |                     |
|                       |       | ADDV           | Binary addition with overflow check                                                   |                     |
|                       |       | CMP/cond       | Comparison                                                                            |                     |
|                       |       | DIV1           | Division                                                                              |                     |
|                       |       | DIV0S          | Initialization of signed division                                                     |                     |
|                       |       | DIV0U          | Initialization of unsigned division                                                   |                     |
|                       |       | DMULS          | Signed double-precision multiplication                                                |                     |
|                       |       | DMULU          | Unsigned double-precision multiplication                                              |                     |
|                       |       | DT             | Decrement and test                                                                    |                     |
|                       |       | EXTS           | Sign extension                                                                        |                     |
|                       |       | EXTU           | Zero extension                                                                        |                     |
|                       |       | MAC            | Multiply-and-accumulate operation, double-precision multiply-and-accumulate operation |                     |

| Classification                  | Types | Operation Code | Function                                       | No. of Instructions |
|---------------------------------|-------|----------------|------------------------------------------------|---------------------|
| Arithmetic operations<br>(cont) | 21    | MUL            | Double-precision multiplication (32 × 32 bits) | 33                  |
|                                 |       | MULS           | Signed multiplication (16 × 16 bits)           |                     |
|                                 |       | MULU           | Unsigned multiplication (16 × 16 bits)         |                     |
|                                 |       | NEG            | Negation                                       |                     |
|                                 |       | NEGC           | Negation with borrow                           |                     |
|                                 |       | SUB            | Binary subtraction                             |                     |
|                                 |       | SUBC           | Binary subtraction with borrow                 |                     |
|                                 |       | SUBV           | Binary subtraction with underflow check        |                     |
| Logic operations                | 6     | AND            | Logical AND                                    | 14                  |
|                                 |       | NOT            | Bit inversion                                  |                     |
|                                 |       | OR             | Logical OR                                     |                     |
|                                 |       | TAS            | Memory test and bit set                        |                     |
|                                 |       | TST            | Logical AND and T bit set                      |                     |
|                                 |       | XOR            | Exclusive OR                                   |                     |
| Shift                           | 12    | ROTL           | One-bit left rotation                          | 16                  |
|                                 |       | ROTR           | One-bit right rotation                         |                     |
|                                 |       | ROTCL          | One-bit left rotation with T bit               |                     |
|                                 |       | ROTCR          | One-bit right rotation with T bit              |                     |
|                                 |       | SHAL           | One-bit arithmetic left shift                  |                     |
|                                 |       | SHAR           | One-bit arithmetic right shift                 |                     |
|                                 |       | SHLL           | One-bit logical left shift                     |                     |
|                                 |       | SHLLn          | n-bit logical left shift                       |                     |
|                                 |       | SHLR           | One-bit logical right shift                    |                     |
|                                 |       | SHLRn          | n-bit logical right shift                      |                     |
|                                 |       | SHAD           | Dynamic arithmetic shift                       |                     |

Notes: \* The number of cycles until the sleep state is entered.

1. The table shows the minimum number of execution cycles. The actual number of instruction execution cycles will increase in cases such as the following:
  - a. When there is contention between an instruction fetch and data access
  - b. When the destination register in a load (memory-to-register) instruction is also used by the next instruction
2. With the addressing modes using displacement (disp) listed below, the assembler descriptions in this manual show the value before scaling ( $\times 1$ ,  $\times 2$ , or  $\times 4$ ) is performed. This is done to clarify the operation of the chip. For the actual assembler descriptions, refer to the individual assembler notation rules.

@ (disp:4, Rn) ;            Register-indirect with displacement

@ (disp:8, Rn) ;            GBR-indirect with displacement

@ (disp:8, PC) ;            PC-relative with displacement

disp:8, disp:12 ;           PC-relative

## 2.4.2 Instruction Code Map

Table 2.11 shows the instruction code map.

**Table 2.11 Instruction Code Map**

| Instruction Code         |      |      |      | Fx: 0000              |             | Fx: 0001          |  | Fx: 0010          |  | Fx: 0011 to 1111 |  |

Note: See the SH-3/SH-3E/SH3-DSP Programming Manual for details.

## 2.5 Processor States and Processor Modes

### 2.5.1 Processor States

The SH7706 has five processor states: the reset state, exception-handling state, bus-released state, program execution state, and power-down state.

**Reset State:** In this state the CPU is reset. The CPU enters the power-on reset state if the  $\overline{\text{RESETP}}$  pin is low, or the manual reset state if the  $\overline{\text{RESETM}}$  pin is low. See section 4, Exception Handling, for more information on resets.

In the power-on reset state, the internal states of the CPU and the on-chip supporting module registers are initialized. In the manual reset state, the internal states of the CPU and registers of on-chip supporting modules other than the bus state controller (BSC) are initialized. Refer to the register descriptions in the relevant sections for further details.

**Exception-Handling State:** This is a transient state during which the CPU's processor state flow is altered by a reset, general exception, or interrupt exception handling.

In the case of a reset, the CPU branches to address H'A0000000 and starts executing the user-coded exception handling program.

In the case of a general exception or interrupt, the program counter (PC) contents are saved in the saved program counter (SPC) and the status register (SR) contents are saved in the saved status register (SSR). The CPU branches to the start address of the user-coded exception service routine found from the sum of the contents of the vector base address and the vector offset. See section 4, Exception Processing, for more information on resets, general exceptions, and interrupts.

**Program Execution State:** In this state the CPU executes program instructions in sequence.

**Power-Down State:** In the power-down state, CPU operation halts and power consumption is reduced. There are three modes in the power-down state: sleep mode, software standby mode and hardware standby mode. The software standby mode and hardware standby mode are expressed by a generic name, standby mode. See section 22, Power-Down Modes, for more information.

**Bus-Released State:** In this state the CPU has released the bus to a device that requested it.

Transitions between the states are shown in figure 2.6.

**Figure 2.6 Processor State Transitions**

### 2.5.2 Processor Modes

There are two processor modes: privileged mode and user mode. The processor mode is determined by the processor mode bit (MD) in the status register (SR). User mode is selected when the MD bit is 0, and privileged mode when the MD bit is 1. When the reset state or exception state is entered, the MD bit is set to 1. When exception handling ends, the MD bit is cleared to 0 and user mode is entered. There are certain registers and bits which can only be accessed in privileged mode.

## Section 3 Memory Management Unit (MMU)

This LSI has an on-chip memory management unit (MMU) that implements address translation. This LSI's features a resident translation look-aside buffer (TLB) that caches information for user-created address translation tables located in external memory. It enables high-speed translation of virtual addresses into physical addresses. Address translation uses the paging system and supports two page sizes (1 Kbytes and 4 Kbytes). The access right to virtual address space can be set for privileged and user modes to provide memory protection.

### 3.1 Role of MMU

The MMU is a feature designed to make efficient use of physical memory. As shown in figure 3.1, if a process is smaller in size than the physical memory, the entire process can be mapped onto physical memory. However, if the process increases in size to the extent that it no longer fits into physical memory, it becomes necessary to partition the process and to map those parts requiring execution onto memory as occasion demands (figure 3.1(1)). Having the process itself consider this mapping onto physical memory would impose a large burden on the process. To lighten this burden, the idea of virtual memory was born as a means of performing en bloc mapping onto physical memory (figure 3.1(2)). In a virtual memory system, substantially more virtual memory than physical memory is provided, and the process is mapped onto this virtual memory. Thus a process only has to consider operation in virtual memory. Mapping from virtual memory to physical memory is handled by the MMU. The MMU is normally controlled by the operating system, switching physical memory to allow the virtual memory required by a process to be mapped onto physical memory in a smooth fashion. Switching of physical memory is carried out via secondary storage, etc.

The virtual memory system that came into being in this way is particularly effective in a time-sharing system (TSS) in which a number of processes are running simultaneously (figure 3.1(3)). If processes running in a TSS had to take mapping onto virtual memory into consideration while running, it would not be possible to increase efficiency. Virtual memory is thus used to reduce this load on the individual processes and so improve efficiency (figure 3.1(4)). In the virtual memory system, virtual memory is allocated to each process. The task of the MMU is to perform efficient mapping of these virtual memory areas onto physical memory. It also has a memory protection feature that prevents one process from inadvertently accessing another process's physical memory.

When address translation from virtual memory to physical memory is performed using the MMU, it may occur that the relevant translation information is not recorded in the MMU, with the result that one process may inadvertently access the virtual memory allocated to another process. In this case, the MMU will generate an exception, change the physical memory mapping, and record the new address translation information.

Although the functions of the MMU could also be implemented by software alone, the need for translation to be performed by software each time a process accesses physical memory would result in poor efficiency. For this reason, a buffer for address translation (translation look-aside buffer: TLB) is provided in hardware to hold frequently used address translation information. The TLB can be described as a cache for storing address translation information. Unlike cache memory, however, if address translation fails, that is, if an exception is generated, switching of address translation information is normally performed by software. This makes it possible for memory management to be performed flexibly by software.

The MMU has two methods of mapping from virtual memory to physical memory: a paging method using fixed-length address translation, and a segment method using variable-length address translation. With the paging method, the unit of translation is a fixed-size address space (usually of 1 to 64 Kbytes) called a page.

In the following text, this LSI's address space in virtual memory is referred to as virtual address space, and address space in physical memory as physical memory space.

**Figure 3.1 MMU Functions**

### 3.1.1 This LSI's MMU

**Virtual Address Map:** This LSI uses 32-bit virtual addresses to access a 4-Gbyte virtual address space that is divided into several areas. Address space mapping is shown in figure 3.2.

In the privileged mode, the virtual address space is divided into five areas.

P0 and P3 areas are mapped to physical address spaces in page units according to the information in the address translation table. Write-back or write-through can be selected for write access by means of a cache control register (CCR) setting.

Mapping of the P1 area is fixed to physical address space (H'00000000 to H'1FFFFFFF). In the P1 area, setting a virtual address MSBs (bit 31) to 0 generates the corresponding physical address. P1 area access can be cached, write-back or write-through can be selected according to the setting of CCR whether to cache or not.

Mapping of the P2 area is fixed to physical address space (H'00000000 to H'1FFFFFFF). In the P2 area, setting the top three virtual address bits (bits 31, 30, and 29) to 0 generates the corresponding physical address. P2 area access cannot be cached.

The P1 and P2 areas are not mapped by the address translation table, so the TLB is not used and no exceptions like TLB misses occur. Initialization of MMU-related registers, exception processing, and the like are located in the P1 and P2 areas. Because the P1 area is cached, handlers that require high-speed processing are placed there.

A part of the control register in the peripheral module is allocated in P2 area.

The P4 area is used for mapping on-chip control register addresses. Address spaces from H'E0000000 to H'FFFFFFF and from H'F4000000 to H'FBFFFFFF are reserved. An operation of this LSI is not guaranteed when these address spaces are accessed. Address space from H'F0000000 to H'F1FFFFFF is assigned to the cache, and address space from H'F2000000 to H'F3FFFFFF is assigned to the TLB. Address space from H'FC000000 to H'FFFFFFF is a space for control registers. However, an operation of this LSI is not guaranteed when an address space that is not assigned to any control register is accessed.

In the user mode, 2 Gbytes of the virtual address space from H'00000000 to H'7FFFFFFF (area U0) can be accessed. U0 is mapped onto physical address space in page units. Write-back or write-through mode can be selected for write accesses by means of CCR setting. 2 Gbytes of the virtual address space from H'80000000 to H'FFFFFFF cannot be accessed in the user mode. Attempting to do so creates a CPU address error. Write-back or write-through can be selected for write access by means of the CCR setting.

**Figure 3.2 Virtual Address Space Mapping**

**Physical Address Space:** This LSI supports a 32-bit physical address space, but the upper 3 bits are actually ignored and treated as a shadow. See section 8, Bus State Controller (BSC), for details.

**Address Translation:** When the MMU is enabled, the virtual address space is divided into units called pages. Physical addresses are translated in page units. Address translation tables in external memory hold information such as the physical address that corresponds to the virtual address and memory protection codes. When an access to areas P1 or P2 occurs, there is no TLB access and the physical address is defined uniquely by hardware. If it belongs to area P0, P3 or U0, the TLB is searched by virtual address and, if that virtual address is registered in the TLB, the access hits the TLB. The corresponding physical address and the page control information are read from the TLB and the physical address is determined.

If the virtual address is not registered in the TLB, a TLB miss exception occurs and processing will shift to the TLB miss handler. In the TLB miss handler, the TLB address translation table in external memory is searched and the corresponding physical address and the page control information are registered in the TLB. After returning from the handler, the instruction that caused the TLB miss is re-executed. When the MMU is enabled, address translation information that results in a physical address space of H'80000000–H'FFFFFFFF should not be registered in the TLB.

When the MMU is disabled, the virtual address is used directly as the physical address. As this LSI supports a 29-bit address space as the physical address space, the top 3 bits of the physical address are ignored, and constitute a shadow space. For example, addresses H'00001000 in the P0 area, H'80001000 in the P1 area, H'A0001000 in the P2 area, and H'C0001000 in the P3 area are all mapped onto the same physical address. When access to these addresses is performed with the cache enabled, an address with the top 3 bits of the physical address masked to 0 is stored in the cache address array to ensure data congruity.

**Single Virtual Memory Mode and Multiple Virtual Memory Mode:** There are two virtual memory modes: single virtual memory mode and multiple virtual memory mode. In single virtual memory mode, multiple processes run in parallel using the virtual address space exclusively and the physical address corresponding to a given virtual address is specified uniquely. In multiple virtual memory mode, multiple processes run in parallel sharing the virtual address space, so a given virtual address may be translated into different physical addresses depending on the process. By the value set to the MMU control register (MMUCR), either single or multiple virtual mode is selected.

In terms of operation, the only difference between single virtual memory mode and multiple virtual memory mode is the TLB address comparison method.

**Address Space Identifier (ASID):** In multiple virtual memory mode, the address space identifier (ASID) is used to differentiate between processes running in parallel and sharing virtual address space. The ASID is 8 bits in length and can be set by software setting of the ASID of the currently running process in page table entry register high (PTEH) within the MMU. When the process is switched using the ASID, the TLB does not have to be purged.

In single virtual memory mode, the ASID is used to provide memory protection for processes running simultaneously and using the virtual address space exclusively.

## 3.2 Register Description

There are five registers for MMU processing. These are located in address space area P4 and can only be accessed from privileged mode by specifying the address.

These registers for MMU processing are shown below. Refer to section 23, List of Registers, for more details of the addresses and access sizes.

- Page table entry register high (PTEH)
- Page table entry register low (PTEL)
- Translation table base register (TTB)
- TLB exception address register (TEA)
- MMU control register (MMUCR)

### 3.2.1 Page Table Entry Register High (PTEH)

The page table entry register high (PTEH) consists of a virtual page number (VPN) and ASID. The VPN is set the VPN of the virtual address at which the exception is generated in case of an MMU exception or CPU address error exception. When the page size is 4 kbytes, the VPN is the upper 20 bits of the virtual address, but in this case the upper 22 bits of the virtual address are set. The VPN can also be modified by software. As the ASID, software sets the number of the currently executing process. The VPN and ASID are recorded in the TLB by the LDTLB instruction.

| Bit      | Bit Name | Initial Value | R/W | Description                                                                      |
|----------|----------|---------------|-----|----------------------------------------------------------------------------------|
| 31 to 10 | VPN      | —             | R/W | Virtual page number                                                              |
| 9, 8     | —        | All 0         | R   | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 7 to 0   | ASID     | —             | R/W | Address space identifier                                                         |

### 3.2.2 Page Table Entry Register Low (PTEL)

The page table entry register low register (PTEL) is used to store the physical page number and page management information to be recorded in the TLB by the LDTLB instruction. The contents of this register are only modified by a software command.

| Bit      | Bit Name | Initial Value | R/W | Description                                                        |
|----------|----------|---------------|-----|--------------------------------------------------------------------|
| 31 to 10 | PPN      | —             | R/W | Physical page number                                               |
| 9        | —        | 0             | R   | Page management information<br>Refer to section 3.3 TLB Functions. |
| 8        | V        | —             | R/W |                                                                    |
| 7        | —        | 0             | R   |                                                                    |
| 6        | PR       | —             | R/W |                                                                    |
| 5        | PR       | —             | R/W |                                                                    |

### 3.2.3 The Translation Table Base Register (TTB)

The translation table base register (TTB) is a 32-bit register. TTB is used to store the base address of the current page table. The contents of this register are only modified in response to a software command. TTB is available to use by software for general purposes.

### 3.2.4 The TLB Exception Address Register (TEA)

The TLB exception address register (TEA) is a 32-bit register. TEA is used to store the virtual address corresponding to a MMU or CPU address error exception after these exceptions has occurred. This value remains valid until the next exception or interrupt occurs.

### 3.2.5 MMU Control Register (MMUCR)

The MMU control register (MMUCR) makes the MMU settings. Any program that modifies MMUCR should reside in the P1 or P2 area.

| Bit     | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

# 3.3 TLB Functions

## 3.3.1 Configuration of the TLB

The TLB caches address translation table information located in the external memory. The address translation table stores the physical page number translated from the virtual page number and the control information for the page, which is the unit of address translation. Figure 3.3 shows the overall TLB configuration. The TLB is 4-way set associative with 128 entries. There are 32 entries for each way. Figure 3.4 shows the configuration of virtual addresses and TLB entries.

Figure 3.3 Overall Configuration of the TLB

**Legend**

- VPN:** Virtual page number. Top 22 bits of virtual address for a 1-kbyte page, or top 20 bits of virtual address for a 4-kbyte page. Since VPN bits 16-12 are used as the index number, they are not stored in the TLB entry.
- ASID:** Address space identifier. Indicates the process that can access a virtual page. In single virtual memory mode and user mode, or in multiple virtual memory mode, if the SH bit is 0, the address is compared with the ASID in PTEH when address comparison is performed.
- SH:** Share status bit  
 0 = Page not shared between processes  
 1 = Page shared between processes
- SZ:** Page-size bit  
 0 = 1-kbyte page  
 1 = 4-kbyte page
- V:** Valid bit. Indicates whether entry is valid.  
 0 = Invalid  
 1 = Valid  
 Cleared to 0 by a power-on reset. Not affected by a manual reset.
- PPN:** Physical page number. Top 22 bits of physical address. PPN bits 11-10 are not used in case of a 4-kbyte page. Attention must be paid to the synonym problem in case of a 1-kbyte page (see section 3.4.4 Avoiding Synonym Problems).
- PR:** Set the most significant bit to 0.  
 Protection key field. 2-bit field encoded to define the access rights to the page.  
 00: Reading only is possible in privileged mode.  
 01: Reading/writing is possible in privileged mode.  
 10: Reading only is possible in privileged/user mode.  
 11: Reading/writing is possible in privileged/user mode.
- C:** Cacheable bit. Indicates whether the page is cacheable.  
 0: Non-cacheable  
 1: Cacheable
- D:** Dirty bit. Indicates whether the page has been written to.  
 0 = Not written to  
 1 = Written to

**Figure 3.4 Virtual Address and TLB Structure**

### 3.3.2 TLB Indexing

The TLB uses a 4-way set associative scheme, so entries must be selected by index. VPN bits 16 to 12 are used as the index number regardless of the page size. The index number can be generated in two different ways depending on the setting of the IX bit in MMUCR.

1. When IX = 0, VPN bits 16 to 12 alone are used as the index number
2. When IX = 1, VPN bits 16 to 12 are EX-ORed with ASID bits 4 to 0 to generate a 5-bit index number

The second method is used to prevent lowered TLB efficiency that results when multiple processes run simultaneously in the same virtual address space (multiple virtual memory) and a specific entry is selected by indexing of each process. Figures 3.5 and 3.6 show the indexing schemes.

**Figure 3.5 TLB Indexing (IX = 1)**

**Figure 3.6 TLB Indexing (IX = 0)**

### 3.3.3 TLB Address Comparison

The results of address comparison determine whether a specific virtual page number is registered in the TLB. The virtual page number of the virtual address that accesses external memory is compared to the virtual page number of the indexed TLB entry. The ASID within the PTEH is compared to the ASID of the indexed TLB entry. All four ways are searched simultaneously. If the compared values match, and the indexed TLB entry is valid (V bit = 1), the hit is registered.

It is necessary to have software ensure that TLB hits do not occur simultaneously in more than one way, as hardware operation is not guaranteed if this occurs. For example, if there are two identical TLB entries with the same VPN and a setting is made such that a TLB hit is made only by a process with ASID = H'FF when one is in the shared state (SH = 1) and the other in the non-shared state (SH = 0), then if the ASID in PTEH is set to H'FF, there is a possibility of simultaneous TLB hits in both these ways. It is therefore necessary to ensure that this kind of setting is not made by software.

The object compared varies depending on the page management information (SZ, SH) in the TLB entry. It also varies depending on whether the system supports multiple virtual memory or single virtual memory.

The page-size information determines whether VPN (11, 10) is compared. VPN (11, 10) is compared for 1-kbyte pages (SZ = 0) but not for 4-kbyte pages (SZ = 1).

The sharing information (SH) determines whether the PTEH.ASID and the ASID in the TLB entry are compared. ASIDs are compared when there is no sharing between processes (SH = 0) but not when there is sharing (SH = 1).

When single virtual memory is supported (MMUCR.SV = 1) and privileged mode is engaged (SR.MD = 1), all process resources can be accessed. This means that ASIDs are not compared when single virtual memory is supported and privileged mode is engaged. The objects of address comparison are shown in figure 3.7.

**Figure 3.7 Objects of Address Comparison**

### 3.3.4 Page Management Information

In addition to the SH and SZ bits, the page management information of TLB entries also includes D, C, and PR bits.

The D bit of a TLB entry indicates whether the page is dirty (i.e., has been written to). If the D bit is 0, an attempt to write to the page results in an initial page write exception. For physical page swapping between secondary memory and main memory, for example, pages are controlled so that a dirty page is paged out of main memory only after that page is written back to secondary memory. To record that there has been a write to a given page in the address translation table in memory, an initial page write exception is used.

The C bit in the entry indicates whether the referenced page resides in a cacheable or non-cacheable area of memory. The PR field specifies the access rights for the page in privileged and user modes and is used to protect memory. Attempts at nonpermitted accesses result in TLB protection violation exceptions.

Access states designated by the D, C, and PR bits are shown in table 3.1.

**Table 3.1 Access States Designated by D, C, and PR Bits**

|        |    | Privileged Mode          |                                    | User Mode                          |                                    |
|--------|----|--------------------------|------------------------------------|------------------------------------|------------------------------------|
|        |    | Reading                  | Writing                            | Reading                            | Writing                            |
| D bit  | 0  | Permitted                | Initial page write exception       | Permitted                          | Initial page write exception       |
|        | 1  | Permitted                | Permitted                          | Permitted                          | Permitted                          |
| C bit  | 0  | Permitted (no caching)   | Permitted (no caching)             | Permitted (no caching)             | Permitted (no caching)             |
|        | 1  | Permitted (with caching) | Permitted (with caching)           | Permitted (with caching)           | Permitted (with caching)           |
| PR bit | 00 | Permitted                | TLB protection violation exception | TLB protection violation exception | TLB protection violation exception |
|        | 01 | Permitted                | Permitted                          | TLB protection violation exception | TLB protection violation exception |
|        | 10 | Permitted                | TLB protection violation exception | Permitted                          | TLB protection violation exception |
|        | 11 | Permitted                | Permitted                          | Permitted                          | Permitted                          |

## 3.4 MMU Functions

### 3.4.1 MMU Hardware Management

There are two kinds of MMU hardware management as follows:

1. The MMU decodes the virtual address accessed by a process and performs address translation by controlling the TLB in accordance with the MMUCR settings.
2. In address translation, the MMU receives page management information from the TLB, and determines the MMU exception and whether the cache is to be accessed (using the C bit). For details of the determination method and the hardware processing, see section 3.5, MMU Exceptions.

### 3.4.2 MMU Software Management

There are three kinds of MMU software management, as follows.

1. MMU register setting. MMUCR setting, in particular, should be performed in areas P1 and P2 for which address translation is not performed. Also, since SV and IX bit changes constitute address translation system changes, in this case, TLB flushing should be performed by simultaneously writing 1 to the TF bit also. Since MMU exceptions are not generated in the MMU disabled state with the AT bit cleared to 0, use in the disabled state must be avoided with software that does not use the MMU.
2. TLB entry recording, deletion, and reading. TLB entry recording can be done in two ways by using the LDTLB instruction, or by writing directly to the memory-mapped TLB. For TLB entry deletion and reading, the memory allocation TLB can be accessed. See section 3.4.3, MMU Instruction (LDTLB), for details of the LDTLB instruction, and section 3.6, Memory-Mapped TLB Configuration, for details of the memory-mapped TLB.
3. MMU exception processing. When an MMU exception is generated, it is handled on the basis of information set from the hardware side. See section 3.5, MMU Exceptions, for details.

When single virtual memory mode is used, it is possible to create a state in which physical memory access is enabled in the privileged mode only by clearing the share status bit (SH) to 0 to specify recording of all TLB entries. This strengthens inter-process memory protection, and enables special access levels to be created in the privileged mode only.

Recording a 1-kbyte page TLB entry may result in a synonym problem. See section 3.4.4, Avoiding Synonym Problems.

### 3.4.3 MMU Instruction (LDTLB)

The load TLB instruction (LDTLB) is used to record TLB entries. When the IX bit in MMUCR is 0, the LDTLB instruction changes the TLB entry in the way specified by the RC bit in MMUCR to the value specified by PTEH and PTEL, using VPN bits 16 to 12 specified in PTEH as the index number. When the IX bit in MMUCR is 1, the EX-OR of VPN bits 16 to 12 specified in PTEH and ASID bits 4 to 0 in PTEH are used as the index number.

Figure 3.8 shows the case where the IX bit in MMUCR is 0.

When an MMU exception occurs, the virtual page number of the virtual address that caused the exception is set in PTEH by hardware. The way is set in the RC bit of MMUCR for each exception according to the rules described in section 3.2.5 MMU Control Register. Consequently, if the LDTLB instruction is issued after setting only PTEL in the MMU exception processing routine, TLB entry recording is possible. Any TLB entry can be updated by software rewriting of PTEH and the RC bits in MMUCR.

As the LDTLB instruction changes address translation information, there is a risk of destroying address translation information if this instruction is issued in the P0, U0, or P3 area. Make sure, therefore, that this instruction is issued in the P1 or P2 area. Also, an instruction associated with an access to the P0, U0, or P3 area (such as the RTE instruction) should be issued at least two instructions after the LDTLB instruction.

**Figure 3.8 Operation of LDTLB Instruction**

### 3.4.4 Avoiding Synonym Problems

When a 1-kbyte page is recorded in a TLB entry, a synonym problem may arise. If a number of virtual addresses are mapped onto a single physical address, the same physical address data will be recorded in a number of cache entries, and it will not be possible to guarantee data congruity. The reason why this problem only occurs when using a 1-kbyte page is explained below with reference to figure 3.9.

To achieve high-speed operation of the SH7706 cache, an index number is created using virtual address bits 11 to 4. When a 4-kbyte page is used, virtual address bits 11 to 4 are included in the offset, and since they are not subject to address translation, they are the same as physical address bits 11 to 4. In cache-based address comparison and recording in the address array, since the cache tag address is a physical address, physical address bits 31 to 10 are recorded.

When a 1-kbyte page is used, also, a cache index number is created using virtual address bits 10 to 4. However, in case of a 1-kbyte page, virtual address bits (11, 10) are subject to address translation and therefore may not be the same as physical address bits 11 and 10. Consequently, the physical address is recorded in a different entry from that of the index number indicated by the physical address in the cache address array.

For example, assume that, with 1-kbyte page TLB entries, TLB entries for which the following translation has been performed are recorded in two TLBs:

|                   |            |   |                  |            |
|-------------------|------------|---|------------------|------------|
| Virtual address 1 | H'00000000 | → | physical address | H'00000C00 |
| Virtual address 2 | H'00000C00 | → | physical address | H'00000C00 |

Virtual address 1 is recorded in cache entry H'00, and virtual address 2 in cache entry H'C0. Since two virtual addresses are recorded in different cache entries despite the fact that the physical addresses are the same, memory inconsistency will occur as soon as a write is performed to either virtual address. Therefore, when recording a 1-kbyte TLB entry, if the physical address is the same as a physical address already used in another TLB entry, it should be recorded in such a way that physical address bits (11, 10) are the same.

When using a 4-kbyte page

Virtual address

Physical address

Virtual address (11 to 4)

Physical address (31 to 10)

Cache address array

When using a 1-kbyte page

**Figure 3.9** Synonym Problem

## 3.5 MMU Exceptions

There are four MMU exceptions: TLB miss, TLB protection violation, TLB invalid, and initial page write.

### 3.5.1 TLB Miss Exception

A TLB miss results when the virtual address and the address array of the selected TLB entry are compared and no match is found. TLB miss exception processing includes both hardware and software operations.

**Hardware Operations:** In a TLB miss, this LSI's hardware executes a set of prescribed operations, as follows:

1. The VPN field of the virtual address causing the exception is written to the PTEH register.
2. The virtual address causing the exception is written to the TEA register.
3. Either exception code H'040 for a load access, or H'060 for a store access, is written to the EXPEVT register.
4. The PC value indicating the address of the instruction in which the exception occurred is written to the save program counter (SPC). If the exception occurred in a delay slot, the PC value indicating the address of the related delayed branch instruction is written to the SPC.
5. The contents of the status register (SR) at the time of the exception are written to the save status register (SSR).
6. The mode (MD) bit in SR is set to 1, and switched to the privileged mode.
7. The block (BL) bit in SR is set to 1 to mask any further exception requests.
8. The register bank (RB) bit in SR is set to 1.
9. The RC field in the MMUCR is incremented by 1 when all entries indexed are valid. When some entries indexed are invalid, the smallest way number of them is set in RC.
10. Execution branches to the address obtained by adding the value of the VBR contents and H'00000400 to invoke the user-written TLB miss exception handler.

**Software (TLB Miss Handler) Operations:** The software searches the page tables in external memory and allocates the required page table entry. Upon retrieving the required page table entry, software must execute the following operations:

1. Write the value of the physical page number (PPN) field and the protection key (PR), page size (SZ), cacheable (C), dirty (D), share status (SH), and valid (V) bits of the page table entry recorded in the address translation table in the external memory into the PTEL register in this LSI.
2. If using software for way selection for entry replacement, write the desired value to the RC field in MMUCR.
3. Issue the LDTLB instruction to load the contents of PTEH and PTEL into the TLB.
4. Issue the return from exception handler (RTE) instruction to terminate the handler routine and return to the instruction stream.

### 3.5.2 TLB Protection Violation Exception

A TLB protection violation exception results when the virtual address and the address array of the selected TLB entry are compared and a valid entry is found to match, but the type of access is not permitted by the access rights specified in the PR field. TLB protection violation exception processing includes both hardware and software operations.

**Hardware Operations:** In a TLB protection violation exception, this LSI's hardware executes a set of prescribed operations, as follows:

1. The VPN field of the virtual address causing the exception is written to the PTEH register.
2. The virtual address causing the exception is written to the TEA register.
3. Either exception code H'0A0 for a load access, or H'0C0 for a store access, is written to the EXPEVT register.
4. The PC value indicating the address of the instruction in which the exception occurred is written into SPC (if the exception occurred in a delay slot, the PC value indicating the address of the related delayed branch instruction is written into SPC).
5. The contents of SR at the time of the exception are written to SSR.
6. The MD bit in SR is set to 1, and switched to the privileged mode.
7. The BL bit in SR is set to 1 to mask any further exception requests.
8. The RB bit in SR is set to 1.
9. The way that generated the exception is set in the RC field in MMUCR.
10. Execution branches to the address obtained by adding the value of the VBR contents and H'00000100 to invoke the TLB protection violation exception handler.

**Software (TLB Protection Violation Handler) Operations:** Software resolves the TLB protection violation and issues the RTE (return from exception handler) instruction to terminate the handler and return to the instruction stream.

### 3.5.3 TLB Invalid Exception

A TLB invalid exception results when the virtual address is compared to a selected TLB entry address array and a match is found but the entry is not valid (the V bit is 0). TLB invalid exception processing includes both hardware and software operations.

**Hardware Operations:** In a TLB invalid exception, this LSI's hardware executes a set of prescribed operations, as follows:

1. The VPN number of the virtual address causing the exception is written to the PTEH register.
2. The virtual address causing the exception is written to the TEA register.
3. The way number causing the exception is written to RC in MMUCR.
4. Either exception code H'040 for a load access, or H'060 for a store access, is written to the EXPEVT register.
5. The PC value indicating the address of the instruction in which the exception occurred is written to the SPC. If the exception occurred in a delay slot, the PC value indicating the address of the delayed branch instruction is written to the SPC.
6. The contents of SR at the time of the exception are written into SSR.
7. The MD bit in SR is set to 1, and switched to the privileged mode.
8. The BL bit in SR is set to 1 to mask any further exception requests.
9. The RB bit in SR is set to 1.
10. Execution branches to the address obtained by adding the value of the VBR contents and H'00000100, and the TLB protection violation exception handler starts.

**Software (TLB Invalid Exception Handler) Operations:** The software searches the page tables in external memory and assigns the required page table entry. Upon retrieving the required page table entry, software must execute the following operations:

1. Write the values of the PPN, PR, SZ, C, D, SH, and V of the page table entry recorded in the external memory to the PTEL register.
2. If using software for way selection for entry replacement, write the desired value to the RC field in MMUCR.
3. Issue the LDTLB instruction to load the contents of PTEH and PTEL into the TLB.
4. Issue the RTE instruction to terminate the handler and return to the instruction stream. The RTE instruction should be issued after two LDTLB instructions.

### 3.5.4 Initial Page Write Exception

An initial page write exception results in a write access when the virtual address and the address array of the selected TLB entry are compared and a valid entry with the appropriate access rights is found to match, but the D (dirty) bit of the entry is 0 (the page has not been written to). Initial page write exception processing includes both hardware and software operations.

**Hardware Operations:** In an initial page write exception, this LSI's hardware executes a set of prescribed operations, as follows:

1. The VPN field of the virtual address causing the exception is written to the PTEH register.
2. The virtual address causing the exception is written to the TEA register.
3. Exception code H'080 is written to the EXPEVT register.
4. The PC value indicating the address of the instruction in which the exception occurred is written to the SPC. If the exception occurred in a delay slot, the PC value indicating the address of the related delayed branch instruction is written to the SPC.
5. The contents of SR at the time of the exception are written to SSR.
6. The MD bit in SR is set to 1, and switched to the privileged mode.
7. The BL bit in SR is set to 1 to mask any further exception requests.
8. The RB bit in SR is set to 1.
9. The way that caused the exception is set in the RC field in MMUCR.
10. Execution branches to the address obtained by adding the value of the VBR contents and H'00000100 to invoke the user-written initial page write exception handler.

**Software (Initial Page Write Handler) Operations:** The software must execute the following operations:

1. Retrieve the required page table entry from external memory.
2. Set the D bit of the page table entry in the external memory to 1.
3. Write the value of the PPN field and the PR, SZ, C, D, SH, and V bits of the page table entry in the external memory to the PTEL register.
4. If using software for way selection for entry replacement, write the desired value to the RC field in MMUCR.
5. Issue the LDTLB instruction to load the contents of PTEH and PTEL into the TLB.
6. Issue the RTE instruction to terminate the handler and return to the instruction stream. The RTE instruction should be issued after two LDTLB instructions.

Figure 3.10 shows the flowchart for MMU exceptions.

**Figure 3.12 MMU Exception Signals in Data Access**

## 3.6 Configuration of the Memory-Mapped TLB

In order for TLB operations to be managed by software, TLB contents can be read or written to in the privileged mode using the MOV instruction. The TLB is assigned to the P4 area in the virtual address space. The TLB address array (VPN, V bit, and ASID) is assigned to H'F2000000 to H'F2FFFFFFF, and the data array (PPN, PR, SZ, C, D, and SH bits) to H'F3000000 to H'F3FFFFFFF. The V bit in the address array can also be accessed from the data array. Only longword access is possible for both the address array and the data array.

### 3.6.1 Address Array

The address array is assigned to H'F2000000 to H'F2FFFFFFF. To access an address array, the 32-bit address field (for read/write operations) and 32-bit data field (for write operations) must be specified. The address field specifies information for selecting the entry to be accessed; the data field specifies the VPN, V bit and ASID to be written to the address array (figure 3.13 (1)).

In the address field, specify the entry address for selecting the entry (bits 16–12), W for selecting the way (bits 9, 8: 00 is way 0, 01 is way 1, 10 is way 2, 11 is way 3) and H'F2 to indicate address array access (bits 31 to 24). The IX bit in MMUCR indicates whether an EX-OR is taken of the entry address and ASID.

When writing, the write is performed to the entry selected with the index address and way.

When reading, the VPN, V bit, and ASID of the entry selected with the index address and way in the format of the data field in figure 3.13 without comparing addresses. 0 is written to data field bits 16 to 12.

To invalidate a specific entry, specify the entry and way, and write 0 to the corresponding V bit.

### 3.6.2 Data Array

The data array is assigned to H'F3000000 to H'F3FFFFFFF. To access a data array, the 32-bit address field (for read/write operations), and 32-bit data field (for write operations) must be specified. These are specified in the general register. The address section specifies information for selecting the entry to be accessed; the data section specifies the longword data to be written to the data array (figure 3.13 (2)).

In the address section, specify the entry address for selecting the entry (bits 16 to 12), W for selecting the way (bits 9, 8: 00 is way 0, 01 is way 1, 10 is way 2, 11 is way 3), and H'F3 to indicate data array access (bits 31 to 24). The IX bit in MMUCR indicates whether an EX-OR is taken of the entry address and ASID.

Both reading and writing use the longword of the data array specified by the entry address and way number. The access size of the data array is fixed at longword.

### (1) TLB Address Array Access

Read access

Write access

Legend

VPN: Virtual page number

ASID: Address space identifier

V: Valid bit

\* : Don't care bit

W: Way (00: Way 0, 01: Way 1, 10: Way 2, 11: Way 3)

### (2) TLB Data Array Access

Read/write access

Legend

PPN: Physical page number

V: Valid bit

PR: Protection key field

SZ: Page-size bit

C: Cacheable bit

D: Dirty bit

SH: Share status bit

\* : Don't care bit

VPN: Virtual page number

X: 0 for read, don't care bit for write

W: Way (00: Way 0, 01: Way 1, 10: Way 2, 11: Way 3)

**Figure 3.13 Specifying Address and Data for Memory-Mapped TLB Access**

### 3.6.3 Usage Examples

**Invalidating Specific Entries:** Specific TLB entries can be invalidated by writing 0 to the entry's V bit. When the A bit is 1, the VPN and ASID specified by the write data is compared to the VPN and ASID within the TLB entry selected by the entry address and data is written to the matching way. If no match is found, there is no operation. R0 specifies the write data and R1 specifies the address.

```
; R0=H'1547 381C R1=H'F201 3000
; MMUCR.IX=0
; VPN(31-17)=B'0001 0101 0100 011 VPN(11-10)=B'10 ASID=B'0001 1100
; corresponding entry association is made from the entry selected by
; the VPN(16-12)=B'1 0011 index, the V bit of the hit way is cleared to
; 0, achieving invalidation.
MOV.L R0,@R1
```

**Reading the Data of a Specific Entry:** This example reads the data section of a specific TLB entry. The bit order indicated in the data field in figure 3.14 (2) is read. R0 specifies the address and the data section of a selected entry is read to R1.

```
; R0=H'F300 4300 VPN(16-12)=B'00100 Way 3
; MOV.L @R0,R1
```

## 3.7 Usage Note

### 3.7.1 Use of Instructions Manipulating MD and BL Bits in SR

Instructions that manipulate the MD or BL bit in register SR (the LDC Rm, SR instruction, LDC @Rm+, SR instruction, and RTE instruction) and the following instruction, or the LDTLB instruction, should be used with the TLB disabled or in a fixed physical address space (the P1 or P2 space).

### 3.7.2 Use of TLB

An erroneous value is set in the RC bit in MMUCR when all of the following conditions are satisfied.

1. MMU is on (AT bit in MMUCR is 1)
2. Same VPN exists in more than one ways in a single entry in a TLB address array
3. TLB exception is generated

VPN is not initialized by a power-on reset or a manual reset. Therefore, two or more VPNs have the same values in a single entry. When an entry in this state is registered to way 3, for example, the state of that entry in the TLB address array becomes as shown below. As a result, the same VPN exists in both way 0 and way 3, and condition 2 above is satisfied.

| After reset |       |   |   | After registered to way 3 |       |   |
|-------------|-------|---|---|---------------------------|-------|---|
| WAY         | VPN   | V |   | WAY                       | VPN   | V |
| 0           | 12345 | 0 | → | 0                         | 12345 | 0 |
| 3           | 12345 | 0 |   | 3                         | 12345 | 1 |

A condition may also be satisfied when the TLB is handled by software. For example, if an entry in the TLB address array is registered to way 3 after way 0 is disabled (V bit is changed from 1 to 0), the state of that entry becomes as shown below. Similar to the above case, the same VPN exists in both way 0 and way 3, and condition 2 above is satisfied.

| After way 0 is disabled |       |   |   | After registered to way 3 |       |   |
|-------------------------|-------|---|---|---------------------------|-------|---|
| WAY                     | VPN   | V |   | WAY                       | VPN   | V |
| 0                       | 12345 | 0 | → | 0                         | 12345 | 0 |
| 3                       | 11111 | 0 |   | 3                         | 12345 | 1 |

To avoid this failure, take the following two countermeasures.

1. After a reset, initialize the upper four bits in VPN to 1 for all entries in the TLB address array until the AT bit in MMUCR is set to 1.
2. When disabling a way in the TLB address array, in addition to clearing the V bit to 0, initialize the upper four bits in VPN to 1.

These countermeasures will prevent VPN from being a target of address translation. Accordingly, condition 3 is not satisfied, and this failure can be avoided.

# Section 4 Exception Processing

## 4.1 Exception Processing Function

Exception processing is separate from normal program processing, and is performed by a routine separate from the normal program. In response to an exception processing request due to abnormal termination of the executing instruction, control is passed to a user-written exception handler. However, in response to an interrupt request, normal program execution continues until the end of the executing instruction. Here, all exceptions other than resets and interrupts will be called general exceptions. There are thus three types of exceptions: resets, general exceptions, and interrupts.

### 4.1.1 Exception Processing Flow

In exception processing, the contents of the program counter (PC) and status register (SR) are saved in the saved program counter (SPC) and saved status register (SSR), respectively, and execution of the exception handler is invoked from a vector address. The return from exception handler (RTE) instruction is issued by the exception handler routine at the completion of the routine, restoring the contents of the PC and SR to return to the processor state at the point of interruption and the address where the exception occurred.

A basic exception processing sequence consists of the following operations:

1. The contents of the PC and SR are saved in the SPC and SSR, respectively.
2. The block (BL) bit in SR is set to 1, masking any subsequent exceptions.
3. The mode (MD) bit in SR is set to 1 to place the SH7706 in the privileged mode.
4. The register bank (RB) bit in SR is set to 1.
5. An exception code identifying the exception event is written to bits 11 to 0 of the exception event (EXPEVT) or interrupt event (INTEVT and INTEVT2) register.
6. Instruction execution jumps to the designated exception processing vector address to invoke the handler routine.

4.1.2 Exception Processing Vector Addresses

The reset vector address is fixed at H'A0000000. The other three events are assigned offsets from the vector base address by software. Translation look-aside buffer (TLB) miss exceptions have an offset from the vector base address of H'00000400. The vector address offset for general exception events other than TLB miss exceptions is H'00000100. The interrupt vector address offset is H'00000600. The vector base address is loaded into the vector base register (VBR) by software. The vector base address should reside in P1 or P2 fixed physical address space. Figure 4.1 shows the relationship between the vector base address, the vector offset, and the vector table.

Figure 4.1 Vector Addresses

In table 4.1, exceptions and their vector addresses are listed by exception type, instruction completion state, relative acceptance priority, relative order of occurrence within an instruction execution sequence and vector address for exceptions and their vector addresses.

Table 4.1 Exception Event Vectors

| Exception Type           | Current Instruction | Exception Event                        | Priority* <sup>1</sup> | Exception Order | Vector Address | Vector Offset |
|--------------------------|---------------------|----------------------------------------|------------------------|-----------------|----------------|---------------|
| Reset                    | Aborted             | Power-on                               | 1                      | —               | H'A00000000    | —             |
|                          |                     | Manual reset                           | 1                      | —               | H'A00000000    | —             |
|                          |                     | H-UDI reset                            | 1                      | —               | H'A00000000    | —             |
| General exception events | Aborted and retried | CPU Address error (instruction access) | 2                      | 1               | —              | H'00000100    |
|                          |                     | TLB miss (instruction access)          | 2                      | 2               | —              | H'00000400    |
|                          |                     | TLB invalid (instruction access)       | 2                      | 3               | —              | H'00000100    |

| Exception Type             | Current Instruction | Exception Event                               | Priority* <sup>1</sup> | Exception Order | Vector Address | Vector Offset |
|----------------------------|---------------------|-----------------------------------------------|------------------------|-----------------|----------------|---------------|
| General exception events   | Aborted and retried | TLB protection violation (instruction access) | 2                      | 4               | —              | H'00000100    |
|                            |                     | General illegal instruction exception         | 2                      | 5               | —              | H'00000100    |
|                            |                     | Illegal slot instruction exception            | 2                      | 5               | —              | H'00000100    |
|                            |                     | CPU_Address error (data access)               | 2                      | 6               | —              | H'00000100    |
|                            |                     | TLB miss (data access not in repeat loop)     | 2                      | 7               | —              | H'00000400    |
|                            |                     | TLB invalid (data access)                     | 2                      | 8               | —              | H'00000100    |
|                            |                     | TLB protection violation (data access)        | 2                      | 9               | —              | H'00000100    |
|                            |                     | Initial page write                            | 2                      | 10              | —              | H'00000100    |
|                            | Completed           | Unconditional trap (TRAPA instruction)        | 2                      | 5               | —              | H'00000100    |
|                            |                     | User breakpoint trap                          | 2                      | n* <sup>2</sup> | —              | H'00000100    |
|                            |                     | DMA address error                             | 2                      | 12              | —              | H'00000100    |
| General interrupt requests | Completed           | Nonmaskable interrupt                         | 3                      | —               | —              | H'00000600    |
|                            |                     | External hardware interrupt                   | 4* <sup>3</sup>        | —               | —              | H'00000600    |
|                            |                     | H-UDI interrupt                               | 4* <sup>3</sup>        | —               | —              | H'00000600    |

- Notes:
1. Priorities are indicated from high to low, 1 being highest and 4 being lowest.
  2. The user defines the break point traps. 1 is a break point before instruction execution and 11 is a break point after instruction execution. For an operand break point, use 11.
  3. Use software to specify relative priorities of external hardware interrupts and peripheral module interrupts (see section 6, Interrupt Controller (INTC)).

### 4.1.3 Acceptance of Exceptions

Processor resets and interrupts are asynchronous events unrelated to the instruction stream. All exception events are prioritized to establish an acceptance order whenever two or more exception events occur simultaneously. If a power-on reset and manual reset occur simultaneously, the power-on reset takes precedence.

All general exception events occur in a relative order in the execution sequence of an instruction (i.e. execution order), but are handled at priority level 2 in instruction-stream order (i.e. program order), where an exception detected in a preceding instruction is accepted prior to an exception detected in a subsequent instruction.

Three general exception events (reserved instruction code exception, unconditional trap, and illegal slot instruction exception) are detected in the decode stage (ID stage) of different instructions and are mutually exclusive events in the instruction pipeline. They have the same execution priority. Figure 4.2 shows the order of general exception acceptance.

**Figure 4.2 Example of Acceptance Order of General Exceptions**

All exceptions other than a reset are detected in the pipeline ID stage, and accepted on instruction boundaries. However, an exception is not accepted between a delayed branch instruction and the delay slot. A re-execution type exception detected in a delay slot is accepted before execution of the delayed branch instruction. A completion type exception detected in a delayed branch instruction or delay slot is accepted after execution of the delayed branch instruction. The delay slot here refers to the next instruction after a delayed unconditional branch instruction, or the next instruction when a delayed conditional branch instruction is true.

#### 4.1.4 Exception Codes

Table 4.2 lists the exception codes written to bits 11 to 0 of the EXPEVT register for reset or general exceptions or the INTEVT and INTEVT2 registers for general interrupt requests to identify each specific exception event. An additional exception register, the TRAPA (TRA) register, is used to hold the 8-bit immediate data in an unconditional trap (TRAPA instruction).

**Table 4.2 Exception Codes**

| Exception Type           | Exception Event                        | Exception Code |
|--------------------------|----------------------------------------|----------------|
| Reset                    | Power-on reset                         | H'000          |
|                          | Manual reset                           | H'020          |
|                          | H-UDI reset                            | H'000          |
| General exception events | TLB miss/invalid exception (load)      | H'040          |
|                          | TLB miss/invalid exception (store)     | H'060          |
|                          | Initial page write exception           | H'080          |
|                          | TLB protection exception (load)        | H'0A0          |
|                          | TLB protection exception (store)       | H'0C0          |
|                          | CPU Address error (load)               | H'0E0          |
|                          | CPU Address error (store)              | H'100          |
|                          | Unconditional trap (TRAPA instruction) | H'160          |
|                          | Reserved instruction code exception    | H'180          |
|                          | Illegal slot instruction exception     | H'1A0          |
|                          | User breakpoint trap                   | H'1E0          |
|                          | DMA address error                      | H'5C0          |

| Exception Type             | Exception Event               | Exception Code |
|----------------------------|-------------------------------|----------------|
| General interrupt requests | Nonmaskable interrupt         | H'1C0          |
|                            | H-UDI interrupt               | H'5E0          |
|                            | External hardware interrupts: |                |
|                            | IRL3–IRL0 = 0000              | H'200          |
|                            | IRL3–IRL0 = 0001              | H'220          |
|                            | IRL3–IRL0 = 0010              | H'240          |
|                            | IRL3–IRL0 = 0011              | H'260          |
|                            | IRL3–IRL0 = 0100              | H'280          |
|                            | IRL3–IRL0 = 0101              | H'2A0          |
|                            | IRL3–IRL0 = 0110              | H'2C0          |
|                            | IRL3–IRL0 = 0111              | H'2E0          |
|                            | IRL3–IRL0 = 1000              | H'300          |
|                            | IRL3–IRL0 = 1001              | H'320          |
|                            | IRL3–IRL0 = 1010              | H'340          |
|                            | IRL3–IRL0 = 1011              | H'360          |
|                            | IRL3–IRL0 = 1100              | H'380          |
|                            | IRL3–IRL0 = 1101              | H'3A0          |
|                            | IRL3–IRL0 = 1110              | H'3C0          |

Note: Exception codes H'120, H'140, and H'3E0 are reserved.

#### 4.1.5 Exception Request and BL Bit

If a general exception event occurs when the BL bit in SR is 1, the CPU's internal registers are set to their post-reset state, other module registers retain their contents prior to the general exception, and a branch is made to the same address (H'A0000000) as for a reset.

If a general interrupt occurs when BL = 1, the request is masked (held pending) and not accepted until the BL bit is cleared to 0 by software. For reentrant exception processing, the SPC and SSR must be saved and the BL bit in SR cleared to 0.

#### 4.1.6 Returning from Exception Processing

The RTE instruction is used to return from exception processing. When RTE is executed, the SPC value is set in the PC, and the SSR value in SR, and the return from exception processing is performed by branching to the SPC address.

If the SPC and SSR have been saved in the external memory, set the BL bit in SR to 1, then restore the SPC and SSR, and issue an RTE instruction.

## 4.2 Register Description

There are four registers related to exception processing. These are peripheral module registers, and therefore reside in area P4. They can be accessed by specifying the address in the privileged mode only.

There are following four registers related to exception processing. Registers with undefined initial values (TRAPA exception register, Interrupt event register, and Interrupt event register 2) should be initialized by software. Refer to section 23, List of Registers, for more details of the addresses and access sizes.

- Exception event register (EXPEVT)
- Interrupt event register (INTEVT)
- Interrupt event register 2 (INTEVT2)
- TRAPA exception register (TRA)

### 4.2.1 Exception Event Register (EXPEVT)

The exception event register (EXPEVT) contains a 12-bit exception code. The exception code set in EXPEVT is that for a reset or general exception event. The exception code is set automatically by hardware when an exception occurs. EXPEVT can also be modified by software.

| Bit      | Bit Name | Initial Value | R/W | Description                                                                      |
|----------|----------|---------------|-----|----------------------------------------------------------------------------------|
| 31 to 12 | —        | 0             | R   | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 11 to 0  | —        | *             | R/W | 12-bit exception code                                                            |

Note:\* H'0000 is set in a power-on reset, and H'020 in a manual reset.

### 4.2.2 Interrupt Event Register (INTEVT)

The interrupt event register (INTEVT) contains a 12-bit interrupt exception code or a code indicating the interrupt priority. Which is set when an interrupt occurs depends on the interrupt source (refer to section 6, Interrupt Controller (INTC)). The exception code or interrupt priority code is set automatically by hardware when an exception occurs. INTEVT can also be modified by software.

| Bit      | Bit Name | Initial Value | R/W | Description                                                                      |
|----------|----------|---------------|-----|----------------------------------------------------------------------------------|
| 31 to 12 | —        | 0             | R   | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 11 to 0  | —        | —             | R/W | 12-bit interrupt exception code or a code indicating the interrupt priority      |

### 4.2.3 Interrupt Event Register 2 (INTEVT2)

The interrupt event register 2 (INTEVT2) contains a 12-bit exception code. The exception code set in INTEVT2 is that for an interrupt request. The exception code is set automatically by hardware when an exception occurs.

| Bit      | Bit Name | Initial Value | R/W | Description                                                                      |
|----------|----------|---------------|-----|----------------------------------------------------------------------------------|
| 31 to 12 | —        | 0             | R   | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 11 to 0  | —        | —             | R/W | 12-bit exception code                                                            |

### 4.2.4 TRAPA Exception Register (TRA)

The TRAPA exception register (TRA) contains 8-bit immediate data (imm) for the TRAPA instruction. TRA is set automatically by hardware when a TRAPA instruction is executed. TRA can also be modified by software.

| Bit      | Bit Name | Initial Value | R/W | Description                                                                      |
|----------|----------|---------------|-----|----------------------------------------------------------------------------------|
| 31 to 10 | —        | 0             | R   | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 9 to 2   | imm      | —             | R/W | 8-bit immediate data                                                             |
| 1        | —        | 0             | R   | Reserved                                                                         |
| 0        | —        | 0             | R   | These bits are always read as 0. The write value should always be 0.             |

## 4.3 Operation

### 4.3.1 Reset

The reset sequence is used to power up or restart the SH7706 from the initialization state. The RESETP signal and RESETM signal are sampled every clock cycle, and in the case of a power-on reset, all processing being executed (excluding the RTC) is suspended, all unfinished events are canceled, and reset processing is executed immediately. In the case of a manual reset, however, reset processing is executed after memory access in progress is completed. The reset sequence consists of the following operations:

1. The MD bit in SR is set to 1 to place the SH7706 in privileged mode.
2. The BL bit in SR is set to 1, masking any subsequent exceptions.
3. The RB bit in SR is set to 1.
4. An encoded value of H'000 in a power-on reset or H'020 in a manual reset is written to bits 11 to 0 of the EXPEVT register to identify the exception event.
5. Instruction execution jumps to the user-written exception handler at address H'A0000000.

### 4.3.2 Interrupts

An interrupt processing request is accepted on completion of the current instruction. The interrupt acceptance sequence consists of the following operations:

1. The contents of the PC and SR are saved in SPC and SSR, respectively.
2. The BL bit in SR is set to 1, masking any subsequent exceptions.
3. The MD bit in SR is set to 1 to place the SH7706 in privileged mode.
4. The RB bit in SR is set to 1.
5. An encoded value identifying the exception event is written to bits 11 to 0 of the INTEVT and INTEVT2 registers.
6. Instruction execution jumps to the vector location designated by the sum of the value of the contents of the VBR and H'00000600 to invoke the exception handler.

### 4.3.3 General Exceptions

When the SH7706 encounters any exception condition other than a reset or interrupt request, it executes the following operations:

1. The contents of the PC and SR are saved in the SPC and SSR, respectively.
2. The BL bit in SR is set to 1, masking any subsequent exceptions.
3. The MD bit in SR is set to 1 to place the SH7706 in privileged mode.
4. The RB bit in SR is set to 1.
5. An encoded value identifying the exception event is written to bits 11 to 0 of the EXPEVT register.
6. Instruction execution jumps to the vector location designated by either the sum of the vector base address and offset H'00000400 in the vector table in a TLB miss trap, or by the sum of the vector base address and offset H'00000100 for exceptions other than TLB miss traps, to invoke the exception handler.

## 4.4 Individual Exception Operations

This section describes the conditions for specific exception processing, and the processor operations.

### 4.4.1 Resets

- Power-On Reset
  - Conditions:  $\overline{\text{RESETP}}$  low
  - Operations: EXPEVT set to H'000, VBR and SR initialized, branch to PC = H'A0000000. Initialization sets the VBR register to H'00000000. In SR, the MD, RB and BL bits are set to 1 and the interrupt mask bits (I3 to I0) are set to B'1111. The CPU and on-chip supporting modules are initialized. For details, refer to section 23, List of Registers. A power-on reset must always be performed when powering on.  
A high level is output from the STATUS0 and STATUS1 pins.
- Manual Reset
  - Conditions:  $\overline{\text{RESETM}}$  low
  - Operations: EXPEVT set to H'020, VBR and SR initialized, branch to PC = H'A0000000. Initialization sets the VBR register to H'00000000. In SR, the MD, RB, and BL bits are set to 1 and the interrupt mask bits (I3 to I0) are set to B'1111. The CPU and on-chip supporting modules are initialized. For details, refer to section 23, List of Registers.  
A high level is output from the STATUS0 and STATUS1 pins.

- H-UDI Reset
  - Conditions: H-UDI reset command input (see section 21, Hitachi User-Debug Interface (H-UDI))
  - Operations: EXPEVT set to H'000, VBR and SR initialized, branch to PC = H'A0000000. Initialization sets the VBR register to H'0000000. In SR, the MD, RB and BL bits are set to 1 and the interrupt mask bits (I3 to I0) are set to B'1111. The CPU and on-chip supporting modules are initialized. For details, refer to section 23, List of Registers.

**Table 4.3 Types of Reset**

| Type           | Conditions for Transition to Reset State | Internal State |                                                   |
|----------------|------------------------------------------|----------------|---------------------------------------------------|
|                |                                          | CPU            | On-Chip Supporting Modules                        |

#### 4.4.2 General Exceptions

- TLB miss exception
  - Conditions: Comparison of TLB addresses shows no address match
  - Operations: The virtual address (32 bits) that caused the exception is set in TEA and the corresponding virtual page number (22 bits) is set in PTEH (31 to 10). The ASID of PTEH indicates the ASID at the time the exception occurred. The RC bit in MMUCR is incremented by one when all ways are valid, or way-0 is set to the RC with top priority when there is invalid way.

The PC and SR of the instruction that generated the exception are saved to the SPC and SSR, respectively. If the exception occurred during a read, H'040 is set in EXPEVT; if the exception occurred during a write, H'060 is set in EXPEVT. The BL, MD and RB bits in SR are set to 1 and a branch occurs to PC = VBR + H'0400.

To speed up TLB miss processing, the offset differs from other exceptions.

- TLB invalid exception
  - Conditions: Comparison of TLB addresses shows address match but V = 0.
  - Operations: The virtual address (32 bits) that caused the exception is set in TEA and the corresponding virtual page number (22 bits) is set in PTEH (31 to 10). The ASID of PTEH indicates the ASID at the time the exception occurred. The way that generated the exception is set in the RC bits in MMUCR.

The PC and SR of the instruction that generated the exception are saved in the SPC and SSR, respectively. If the exception occurred during a read, H'040 is set in EXPEVT; if the exception occurred during a write, H'060 is set in EXPEVT. The BL, MD, and RB bits in SR are set to 1 and a branch occurs to PC = VBR + H'0100.

- Initial page write exception
  - Conditions: A hit occurred to the TLB for a store access, but  $D = 0$ .  
This occurs for initial writes to the page registered by the load.
  - Operations: The virtual address (32 bits) that caused the exception is set in TEA and the corresponding virtual page number (22 bits) is set in PTEH (31 to 10). The ASID of PTEH indicates the ASID at the time the exception occurred. The way that generated the exception is set in the RC bit in MMUCR.

The PC and SR of the instruction that generated the exception are saved to the SPC and SSR, respectively. H'080 is set in EXPEVT. The BL, MD, and RB bits in SR are set to 1 and a branch occurs in  $PC = VBR + H'0100$ .

- TLB protection exception
  - Conditions: When a hit access violates the TLB protection information (PR bits) shown below:

| PR | Privileged mode    | User mode          |
|----|--------------------|--------------------|
| 00 | Only read enabled  | No access          |
| 01 | Read/write enabled | No access          |
| 10 | Only read enabled  | Only read enabled  |
| 11 | Read/write enabled | Read/write enabled |

- Operations: The virtual address (32 bits) that caused the exception is set in TEA and the corresponding virtual page number (22 bits) is set in PTEH (31 to 10). The ASID of PTEH indicates the ASID at the time the exception occurred. The way that generated the exception is set in the RC bits in MMUCR.

The PC and SR of the instruction that generated the exception are saved to the SPC and SSR, respectively. If the exception occurred during a read, H'0A0 is set in EXPEVT; if the exception occurred during a write, H'0C0 is set in EXPEVT. The BL, MD, and RB bits in SR are set to 1 and a branch occurs to  $PC = VBR + H'0100$ .

- Address error
  - Conditions: When corresponded to the following items.
    - A. Instruction fetch from odd address ( $4n + 1$ ,  $4n + 3$ )
    - B. Word data accessed from addresses other than word boundaries ( $4n + 1$ ,  $4n + 3$ )
    - C. Longword accessed from addresses other than longword boundaries ( $4n + 1$ ,  $4n + 2$ ,  $4n + 3$ )
    - D. Virtual space accessed in user mode in the area H'80000000 to H'FFFFFFF.

- Operations: The virtual address (32 bits) that caused the exception is set in TEA. The PC and SR of the instruction that generated the exception are saved to the SPC and SSR, respectively. If the exception occurred during a read, H'0E0 is set in EXPEVT; if the exception occurred during a write, H'100 is set in EXPEVT. The BL, MD, and RB bits in SR are set to 1 and a branch occurs to  $PC = VBR + H'0100$ . Refer to section 3.5.5, Processing Flow in Event of MMU Exception (Same Processing Flow for CPU Address Error)
- Unconditional trap
  - Conditions: TRAPA instruction executed
  - Operations: The exception is a processing-completion type, so the PC of the instruction after the TRAPA instruction is saved to the SPC. SR from the time when the TRAPA instruction was executing is saved to SSR. The 8-bit immediate value in the TRAPA instruction is quadrupled and set in TRA (9 to 0). H'160 is set in EXPEVT. The BL, MD, and RB bits in SR are set to 1 and a branch occurs to  $PC = VBR + H'0100$ .
- General illegal instruction exception
  - Conditions: When corresponded to the following items.
    - A. When undefined code not in a delay slot is decoded
 

Delay branch instructions: JMP, JSR, BRA, BRAF, BSR, BSRF, RTS, RTE, BT/S, BF/S

Undefined instruction: H'Fxxx. (In the case of SR.CL = 1, the value should be B'111111xxxxxxxxxx.)
    - B. When a privileged instruction not in a delay slot is decoded in user mode
 

Privileged instructions: LDC, STC, RTE, LDTLB, SLEEP; instructions that access GBR with LDC/STC are not privileged instructions.
  - Operations: The PC and SR of the instruction that generated the exception are saved to the SPC and SSR, respectively. H'180 is set in EXPEVT. The BL, MD, and RB bits in SR are set to 1 and a branch occurs to  $PC = VBR + H'0100$ . When an undefined instruction other than H'Fxxx is decoded, operation cannot be guaranteed.
- Illegal slot instruction exception
  - Conditions: When corresponded to the following items.
    - A. When undefined code in a delay slot is decoded
 

Delay branch instructions: JMP, JSR, BRA, BRAF, BSR, BSRF, RTS, RTE, BT/S, BF/S

Undefined instruction: H'Fxxx. (In the case of SR.CL = 1, the value should be B'111111xxxxxxxxxx.)
    - B. When an instruction that rewrites the PC in a delay slot is decoded
 

Instructions that rewrite the PC: JMP, JSR, BRA, BRAF, BSR, BSRF, RTS, RTE, BT, BF, BT/S, BF/S, TRAPA, LDC Rm, SR, LDC.L @Rm+, SR
    - C. When a privileged instruction in a delay slot is decoded in user mode
 

Privileged instructions: LDC, STC, RTE, LDTLB, SLEEP; instructions that access GBR with LDC/STC are not privileged instructions.

- Operations: The PC of the previous delay branch instruction is saved to the SPC. SR of the instruction that generated the exception is saved to SSR. H'1A0 is set in EXPEVT. The BL, MD, and RB bits in SR are set to 1 and a branch occurs to  $PC = VBR + H'0100$ . When an undefined instruction other than H'Fxxx is decoded, operation cannot be guaranteed.
- User break point trap
  - Conditions: When a break condition set in the user break point controller is satisfied
  - Operations: When a post-execution break occurs, the PC of the instruction immediately after the instruction that set the break point is set in the SPC. If a pre-execution break occurs, the PC of the instruction that set the break point is set in the SPC. SR when the break occurs is set in SSR. H'1E0 is set in EXPEVT. The BL, MD, and RB bits in SR are set to 1 and a branch occurs to  $PC = VBR + H'0100$ . See section 7, User Break Controller, for more information.
- DMA Address error
  - Conditions: When corresponded to the following items.
    - A. Word data accessed from addresses other than word boundaries ( $4n + 1, 4n + 3$ )
    - B. Longword accessed from addresses other than longword boundaries ( $4n + 1, 4n + 2, 4n + 3$ )
  - Operations: The PC of the instruction immediately after the instruction executed before the exception occurs is saved to the SPC. SR when the exception occurs is saved to SSR. H'5C0 is set in EXPEVT. The BL, MD, and RB bits in SR are set to 1 and a branch occurs to  $PC = VBR + H'0100$ .

### 4.4.3 Interrupts

#### 1. NMI

Conditions: NMI pin edge detection

Operations: The PC and SR after the instruction that receives the interrupt are saved to the SPC and SSR, respectively. H'01C0 is set to INTEVT and INTEVT2. The BL, MD, and RB bits of the SR are set to 1 and a branch occurs to  $PC = VBR + H'0600$ . This interrupt is not masked by SR.IMASK and received with top priority when the SR's BL bit in SR is 0. When the BL bit is 1, the interrupt is masked. When BLMSK in ICRI is a logic zero and not masked when BLMSK in ICRI is a logic one. See section 6, Interrupt Controller (INTC), for more information.

## 2. IRL Interrupts

Conditions: The value of the interrupt mask bits in SR is lower than the IRL3 to IRL0 level and the BL bit in SR is 0. The interrupt is accepted at an instruction boundary.

Operations: The PC after the instruction that accepts the interrupt is saved to the SPC. SR at the time the interrupt is accepted is saved to SSR. The code corresponding to the IRL3 to IRL0 level is set in INTEVT and INTEVT2. The corresponding code is given as  $H'200 + B' (IRL3-IRL0) \times H'20$ . See table 6.4, Interrupt Exception Handling Source and Priority for the corresponding code. The BL, MD, and RB bits in SR are set to 1 and a branch occurs to  $VBR + H'0600$ . The received level is not set in the interrupt mask bit of SR. See section 6, Interrupt Controller (INTC), for more information.

## 3. IRQ Pin Interrupts

Conditions: IRQ pin is asserted and the interrupt mask bit of SR is lower than the IRQ priority level and the BL bit in SR is 0. The interrupt is accepted at an instruction boundary.

Operations: The PC after the instruction that accepts the interrupt is saved to the SPC. The SR at the point the interrupt is accepted is saved to the SSR. The code corresponding to the interrupt source is set to INTEVT and INTEVT2. The BL, MD, and RB bits of the SR are set to 1 and a branch occurs to  $VBR + H'0600$ . The received level is not set to the interrupt mask bit of SR. See section 6, Interrupt Controller (INTC), for more information.

## 4. On-Chip Peripheral Module Interrupts

Conditions: The interrupt mask bit of SR is lower than the on-chip peripheral module (TMU, RTC, SCI0, SCI2, A/D, LCDC, PCC, DMAC, WDT, REF) interrupt level and the BL bit in SR is 0. The interrupt is accepted at an instruction boundary.

Operations: The PC after the instruction that accepts the interrupt is saved to the SPC. The SR at the point the interrupt is accepted is saved to the SSR. The code corresponding to the interrupt source is set to INTEVT and INTEVT2. The BL, MD, and RB bits of the SR are set to 1 and a branch occurs to  $VBR + H'0600$ . See section 6, Interrupt Controller (INTC), for more information.

## 5. H-UDI Interrupt

Conditions: H-UDI interrupt command is input (see section 21.4.4, H-UDI Interrupt) and the interrupt mask bit of SR is lower than 15 and the BL bit in SR is 0. The interrupt is accepted at an instruction boundary.

Operations: The PC after the instruction that accepts the interrupt is saved to the SPC. The SR at the point the interrupt is accepted is saved to the SSR. H'5E0 is set to INTEVT and INTEVT2. The BL, MD, and RB bits of the SR are set to 1 and a branch occurs to  $VBR + H'0600$ . See section 6, Interrupt Controller (INTC), for more information.

## 4.5 Usage Note

- Return from exception processing
  - Check the BL bit in SR with software. When the SPC and SSR have been saved to external memory, set the BL bit in SR to 1 before restoring them.
  - Issue an RTE instruction. Set the SPC in the PC and SSR in SR with the RTE instruction, branch to the SPC address, and return from exception processing.
- Operation when exception or interrupt occurs while SR.BL = 1
  - Interrupt: Acceptance is suppressed until the BL bit in SR is set to 0 by software. If there is a request and the reception conditions are satisfied, the interrupt is accepted after the execution of the instruction that sets the BL bit in SR to 0. During the sleep or standby mode, however, the interrupt will be accepted even when the BL bit in SR is 1.  
NMI is accepted when BLMSK in ICR1 is 1.
  - Exception: No user break point trap will occur even when the break conditions are met. When one of the other exceptions occurs, a branch is made to the fixed address of the reset (H'A0000000). In this case, the values of the EXPEVT, SPC, and SSR registers are undefined.  
Differently from general reset processing, no signal is output from STATUS0 and STATUS1.
- SPC when an Exception Occurs: The PC saved to the SPC when an exception occurs is as shown below:
  - Re-executing-type exceptions: The PC of the instruction that caused the exception is set in the SPC and re-executed after return from exception processing. If the exception occurred in a delay slot, however, the PC of the immediately prior delayed branch instruction is set in the SPC. If the condition of the conditional delayed branch instruction is not satisfied, the delay slot PC is set in SPC.
  - Completed-type exceptions and interrupts: The PC of the instruction after the one that caused the exception is set in the SPC. If the exception was caused by a delayed conditional instruction, however, the branch destination PC is set in SPC. If the condition of the conditional delayed branch instruction is not satisfied, the delay slot PC is set in SPC.
- Initial register values after reset
  - Undefined registers  
R0\_BANK0/1 to R7\_BANK0/1, R8 to R15, GBR, SPC, SSR, MACH, MACL, PR
  - Initialized registers  
VBR = H'00000000  
SR.MD = 1, SR.BL = 1, SR.RB = 1, SR.I3 to SR.I0 = H'F, SR.CL = 0. Other SR bits are undefined.  
PC = H'A0000000

- Ensure that an exception is not generated at an RTE instruction delay slot, as operation is not guaranteed in this case.
- When the BL bit in the SR register is set to 1, ensure that a TLB-related exception or address error does not occur at an LDC instruction that updates the SR register and the following instruction. This occurrence will be identified as multiple exceptions, and may initiate reset processing.

# Section 5 Cache

## 5.1 Feature

- Instruction/data mixed, 16-byte cache
- 256 entries/way, 4-way set associative, 16-byte block
- Write-back/write-through selectable
- LRU replacing algorithm
- 1-stage write-back buffer
- A maximum of two ways lockable

### 5.1.1 Cache Structure

The cache uses a 4-way set associative system. It is composed of four ways (banks), each of which is divided into an address section and a data section. Each of the address and data sections is divided into 256 entries. The data section of the entry is called a line. Each line consists of 16 bytes (4 bytes  $\times$  4). The data capacity per way is 4 kbytes (16 bytes  $\times$  256 entries), with a total of 16 kbytes in the cache as a whole (4 ways). Figure 5.1 shows the cache structure.

Figure 5.1 Cache Structure

**Address Array:** The V bit indicates whether the entry data is valid. When the V bit is 1, data is valid; when 0, data is not valid. The U bit indicates whether the entry has been written to in write-back mode. When the U bit is 1, the entry has been written to; when 0, it has not. The address tag holds the physical address used in the external memory access. It is composed of 22 bits (address bits 31 to 10) used for comparison during cache searches.

In the SH7706, the top three of 32 physical address bits are used as shadow bits (see section 8, Bus State Controller (BSC)), and therefore in a normal replace operation the top three bits of the tag address are cleared to 0.

The V and U bits are initialized to 0 by a power-on reset, but are not initialized by a manual reset. The tag address is not initialized by either a power-on or manual reset.

**Data Array:** Holds a 16-byte instruction or data. Entries are registered in the cache in line units (16 bytes). The data array is not initialized by a power-on or manual reset.

**LRU:** With the 4-way set associative system, up to four instructions or data with the same entry address (address bits 11 to 4) can be registered in the cache. When an entry is registered, the LRU bits show which of the four ways it is recorded in. There are six LRU bits, controlled by hardware. A least recently used (LRU) algorithm, which selects the way that has been used least recently, is used to select the way.

The LRU bits also indicate the way to be replaced when a cache miss occurs. Table 5.1 shows the relationship between the LRU bits and the way to be replaced when cache locking mechanism is disabled. (For details on the case when cache locking mechanism is enabled, see section 5.2.2, Cache Control Register 2). If a bit pattern other than those listed in table 5.1 is set in the LRU bits by software, the cache will not function correctly. When modifying the LRU bits by software, set one of the patterns listed in table 5.1.

The LRU bits are initialized to 000000 by a power on reset, but are not initialized by a manual reset.

**Table 5.1 LRU and Way Replacement**

| LRU (5 to 0)                                   | Way to be Replaced (when cache locking mechanism is disabled) |
|------------------------------------------------|---------------------------------------------------------------|
| 000000, 000100, 010100, 100000, 110000, 110100 | 3                                                             |
| 000001, 000011, 001011, 100001, 101001, 101011 | 2                                                             |
| 000110, 000111, 001111, 010110, 011110, 011111 | 1                                                             |
| 111000, 111001, 111011, 111100, 111110, 111111 | 0                                                             |

## 5.2 Register Description

The cache includes the following registers. Refer to section 23, List of Registers, for more details of the addresses and access sizes.

- Cache control register (CCR)
- Cache control register 2 (CCR2)

### 5.2.1 Cache Control Register (CCR)

The cache is enabled or disabled using the CE bit of the cache control register (CCR). CCR also has a CF bit (which invalidates all cache entries), and a WT and CB bits (which select either write-through mode or write-back mode). Programs that change the contents of the CCR register should be placed in address space that is not cached.

| Bit     | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                   |
|---------|----------|---------------|-----|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 4 | —        | 0             | R   | Reserved<br>These bits are always read as 0. The write value should always be 0.                                                                                                                              |
| 3       | CF       | 0             | R   | Cache Flash<br>When 1 is set, the V, U and LRU bits of all cache entries are cleared to 0 (flush).<br>This bit is always read as 0. Write-back to external memory is not performed when the cache is flushed. |
| 2       | CB       | 0             | R/W | Cache Write-back<br>Indicates the cache's operating mode for area P1.<br>0: Write-through mode<br>1: Write-back mode                                                                                          |
| 1       | WT       | 0             | R/W | Write through<br>Indicates the cache's operating mode for area P0, U0, and P3.<br>0: Write-back mode<br>1: Write-through mode                                                                                 |
| 0       | CE       | 0             | R/W | Cache enable<br>Indicates whether to use the cache function.<br>0: Cache not used<br>1: Cache used.                                                                                                           |

## 5.2.2 Cache Control Register 2 (CCR2)

Cache control register 2 (CCR2) enables or disables the cache locking mechanism. This register setting is valid only in cache locking mode. Cache locking mode is enabled when the cache locking bit (bit 12) of the status register (SR) is set to 1, and disabled when it is cleared to 0.

If a cache miss occurs during prefetch instruction (PREF) execution in cache locking mode, one line size of data pointed by Rn is loaded into the cache according to the W3LOAD, W3LOCK, W2LOAD, and W2LOCK bit settings of CCR2 (bits 9, 8, 1, and 0). Table 5.2 shows the relationship between each bit setting and the way to be replaced when the prefetch instruction is executed. On the other hand, if a cache hit occurs during prefetch instruction (PREF) execution, no data is loaded into the cache and entries that have been valid in the cache are maintained. For instance, if one line size of data pointed by Rn exists at way 0, and if the prefetch instruction is executed while the cache lock, W3LOAD, and W3LOCK are set to 1s, a cache hit occurs and data is not brought to way 3.

When a cache is accessed by other than the prefetch instruction in cache locking mode, the ways to be replaced are controlled by the W3LOCK and W2LOCK bit settings. Table 5.3 shows the relationship between CCR2 bit settings and the way to be replaced.

A program to modify the CCR2 contents should be placed at an address area whose data is not cached.

| Bit      | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                     |
|----------|----------|---------------|-----|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 10 | —        | All 0         | R   | Reserved<br>These bits are always read as 0. The write value should always be 0.                                                                                                                                |
| 9        | W3LOAD   | 0             | W   | W3LOAD: Way 3 load                                                                                                                                                                                              |
| 8        | W3LOCK   |               | W   | W3LOCK: Way 3 Lock<br>When W3LOACK = 1 & W3LOAD = 1 & SR.CL is 1, the prefetched data will always be loaded into Way3. In all other conditions, the prefetched data will be loaded into the way pointed by LRU. |
| 7 to 2   | —        | All 0         | R   | Reserved<br>These bits are always read as 0. The write value should always be 0.                                                                                                                                |
| 1        | W2LOAD   | 0             | W   | W3LOAD: Way 2 load                                                                                                                                                                                              |
| 0        | W2LOCK   |               | W   | W3LOCK: Way 2 Lock<br>When W3LOACK = 1 & W3LOAD = 1 & SR.CL is 1, the prefetched data will always be loaded into Way2. In all other conditions, the prefetched data will be loaded into the way pointed by LRU. |

Note: Do not set 1 into W2LOAD and W3LOAD at the same time.

Whenever CCR2 bit 8 (W3LOCK) or bit 0 (W2LOCK) is high level the cache is locked. The locked data will not be overwritten unless W3LOCK bit and W2LOCK bit are reset or the PREF condition during cache locking mode watches. During cache locking mode, the LRU in table 5.1 will be replaced by tables 5.4 to 5.6.

**Table 5.2 Way to be Replaced when Cache Miss Occurs during PREF Instruction Execution**

| CL bit | W3LOAD | W3LOCK | W2LOAD | W2LOCK | Way to be Replaced           |
|--------|--------|--------|--------|--------|------------------------------|
| 0      | *      | *      | *      | *      | According to LRU (table 5.1) |
| 1      | *      | 0      | *      | 0      | According to LRU (table 5.1) |
| 1      | *      | 0      | 0      | 1      | According to LRU (table 5.4) |
| 1      | 0      | 1      | *      | 0      | According to LRU (table 5.5) |
| 1      | 0      | 1      | 0      | 1      | According to LRU (table 5.6) |
| 1      | 0      | *      | 1      | 1      | Way 2                        |
| 1      | 1      | 1      | 0      | *      | Way 3                        |

Note: \* Don't care

Do not set 1 into W2LOAD and W3LOAD at the same time.

**Table 5.3 Way to be Replaced when Cache Miss Occurs during Execution of Instruction other than PREF Instruction**

| CL bit | W3LOAD | W3LOCK | W2LOAD | W2LOCK | Way to be Replaced           |
|--------|--------|--------|--------|--------|------------------------------|
| 0      | *      | *      | *      | *      | According to LRU (table 5.1) |
| 1      | *      | 0      | *      | 0      | According to LRU (table 5.1) |
| 1      | *      | 0      | *      | 1      | According to LRU (table 5.4) |

## 5.3 Operation

### 5.3.1 Searching the Cache

If the cache is enabled, whenever instructions or data in memory are accessed the cache will be searched to see if the desired instruction or data is in the cache. Figure 5.2 illustrates the method by which the cache is searched. The cache is a physical cache and holds physical addresses in its address section.

Entries are selected using bits 11 to 4 of the address (virtual) of the access to memory and the address tag of that entry is read. In parallel to reading of the address tag, the virtual address is translated to a physical address in the MMU. The physical address after translation and the physical address read from the address section are compared. The address comparison uses all four ways. When the comparison shows a match and the selected entry is valid ( $V = 1$ ), a cache hit occurs. When the comparison does not show a match or the selected entry is not valid ( $V = 0$ ), a cache miss occurs.

**Figure 5.2 Cache Search Scheme (Normal Mode)**

### 5.3.2 Read Access

**Read Hit:** In a read access, instructions and data are transferred from the cache to the CPU. The LRU is updated.

**Read Miss:** An external bus cycle starts and the entry is updated. The way replaced is shown in table 5.3. Entries are updated in 16-byte units. When the desired instruction or data that caused the miss is loaded from external memory to the cache, the instruction or data is transferred to the CPU in parallel with being loaded to the cache. When it is loaded in the cache, the U bit is cleared to 0 and the V bit is set to 1.

5.3.3 Prefetch Operation

**Prefetch Hit:** LRU is updated so that the way that has been hit to be the latest. Other contents of the cache are not updated. Instruction or data is not transferred to the CPU.

**Prefetch Miss:** Instruction or data is not transferred to the CPU. The way to be replaced is listed in table 5.2. Other operations are same as those in read miss.

5.3.4 Write Access

**Write Hit:** In a write access in the write-back mode, the data is written to the cache and the U bit of the entry written is set to 1. Writing occurs only to the cache; no external memory write cycle is issued. In the write-through mode, the data is written to the cache and an external memory write cycle is issued.

**Write Miss:** In the write-back mode, an external write cycle starts when a write miss occurs, and the entry is updated. The way to be replaced is shown in table5.3. When the U bit of the entry to be replaced is 1, the cache fill cycle starts after the entry is transferred to the write-back buffer. The write-back unit is 16 bytes. Data is written to the cache and the U bit and V bit are set to 1. After the cache completes its fill cycle, the write-back buffer writes back the entry to the memory. In the write-through mode, no write to cache occurs in a write miss; the write is only to the external memory.

5.3.5 Write-Back Buffer

When the U bit of the entry to be replaced in the write-back mode is 1, it must be written back to the external memory. To increase performance, the entry to be replaced is first transferred to the write-back buffer and fetching of new entries to the cache takes priority over writing back to the external memory. After fetching of new entries to the cache is completed, the data in the write-back buffer is write back to the external memory. During the write back cycles, the cache can be accessed. The write-back buffer can hold one line of the cache data (16 bytes) and its physical address. Figure 5.3 shows the configuration of the write-back buffer.

Figure 5.3 Write-Back Buffer Configuration

### 5.3.6 Coherency of Cache and External Memory

Use software to ensure coherency between the cache and the external memory. To allocate memory shared by this LSI and the external device to an address area to be cached, invalidate the entries by operating the memory allocating cache as required. If necessary, for the memory shared by the CPU and the direct memory access controller in this LSI, invalidation must also be performed in the same way as described above.

## 5.4 Memory-Mapped Cache

To allow software management of the cache, cache contents can be read and written by means of MOV instructions in the privileged mode. The cache is mapped onto the P4 area in virtual address space. The address array is mapped onto addresses H'F0000000 to H'F0FFFFFFF, and the data array onto addresses H'F1000000 to H'F1FFFFFFF. Only longword can be used as the access size for the address array and data array, and instruction fetches cannot be performed.

### 5.4.1 Address Array

The address array is mapped onto H'F0000000 to H'F0FFFFFFF. To access an address array, the 32-bit address field (for read/write accesses) and 32-bit data field (for write accesses) must be specified. The address field specifies information for selecting the entry to be accessed; the data field specifies the tag address, V bit, U bit, and LRU bits to be written to the address array (figure 5.4 (1)).

In the address field, specify the entry address for selecting the entry (bits 11 to 4), W for selecting the way (bits 13 and 12: 00 is way 0, 01 is way 1, 10 is way 2, and 11 is way 3), A for selecting the associative operation (bit 3), and H'F0 to indicate address array access (bits 31 to 24).

In data field, specify the tag address (bits 31 to 10), LRU bits (bits 9 to 4), U bit (bit 1), and V bit (bit 0). Upper three bits of the tag address (bits 31 to 29) should always be 0.

The following three operations are enabled for the address array.

**Address Array Read:** Read the tag address, LRU bits, U bit, and V bit of the entry specified by the entry address and the way number. When reading, no associative operation is performed regardless of the value of the associative bit (bit A) specified in the address.

**Address Array Write (without associative operation):** Write the tag address, LRU bits, U bit, and V bit specified in the data field to the entry specified by the entry address and the way number. The associative bit (bit A) should be 0. If data is written to the cache line in which U and V bits are set to 1, the cache line is written back, and then the tag address, LRU bits, U bit, and V bit specified in the data field are written to. However, when 0 is written to the V bit, 0 must also be written to the U bit of that entry.

**Address Array Write (with associative operation):** When writing while the associative bit (bit A) is 1, the addresses of four entries selected by the entry addresses are compared to the tag addresses specified in the data field. As a result of the comparison, U bit and V bit specified in the data field are written to the entry for the hit way. Note however, that the tag address and LRU bits are not changed. When no ways are hit, nothing is written to the address array and no operation occurs. This operation is used to invalidate a specific entry of the cache. When the U bit of the hit entry is 1, write back is occurs. However, when 0 is written to the V bit, 0 must also be written to the U bit of that entry.

## 5.4.2 Data Array

The data array is mapped onto H'F1000000 to H'F1FFFFFF. To access a data array, the 32-bit address field (for read/write accesses) and 32-bit data field (for write accesses) must be specified. The address field specifies information for selecting the entry to be accessed; the data field specifies the longword data to be written to the data array.

In the address field, specify the entry address for selecting the entry (bits 11 to 4), L indicating the longword position within the (16-byte) line (bits 3 and 2: 00 is longword 0, 01 is longword 1, 10 is longword 2, and 11 is longword 3), W for selecting the way (bits 13 and 12: 00 is way 0, 01 is way 1, 10 is way 2, and 11 is way 3), and H'F1 to indicate data array access (bits 31 to 24).

The access size of the data array is fixed at longword, so 00 should be specified to bits 1 and 0 in the address field.

The following two operations are enabled for data array. However, information of the address array is not changed by the following operations.

**Data Array Read:** Reads data specified by L (bits 3 and 2) in the address field from the entry specified by the entry address and the way number.

**Data Array Write:** Writes a longword data specified by the data field to the position specified by L (bits 3 and 2) in the address field from the entry specified by the entry address and the way number.

**Figure 5.4 Specifying Address and Data for Memory-Mapped Cache Access**

### 5.4.3 Usage Examples

#### 1. Invalidating Specific Entries

Specific cache entries can be invalidated by writing 0 to the entry's U and V bit. When the A bit is 1, the address tag specified by the write data is compared to the address tag within the cache selected by the entry address, and data is written when a match is found. If no match is found, there is no operation. When the V bit of the entry is 1, a write back occurs.

```
; R0=H'01100010; VPN=B'0000 0001 0001 0000 0000 00, U=0, V=0
; R1=H'F0000088; address array access, entry=B'00001000, A=1
;
MOV.L R0,@R1
```

#### 2. Reading the Data of a Specific Entry

This example reads the data section of a specific cache entry. The longword indicated in the data field of the data array in figure 5.6 is read to the register.

```
; R1=H'F100 004C; data array access, entry=B'00000100, Way = 0,
; longword address = 3
;
MOV.L @R0,R1 ; Longword 3 is read.
```

## Section 6 Interrupt Controller (INTC)

The interrupt controller (INTC) ascertains the priority of interrupt sources and controls interrupt requests to the CPU. The INTC has registers for setting the priority of each interrupt, and interrupt requests are handled according to the priorities set in these registers.

### 6.1 Feature

INTC has the following features:

- 16 levels of interrupt priority can be set: By setting the five interrupt-priority registers, the priorities of on-chip peripheral module, IRQ interrupts can be selected from 16 levels for individual request sources.
- NMI noise canceler function: NMI input-level bit indicates NMI pin states. By reading this bit in the interrupt exception service routine, the pin state can be checked, enabling it to be used as a noise canceler.
- External devices can be notified that an interrupt has been received ( $\overline{\text{IRQOUT}}$ ): When the SH7706 has released the bus right, the external bus master can be notified that an external interrupt, an on-chip peripheral module interrupt or a memory refresh request has occurred, enabling this LSI to request the bus right.

Figure 6.1 is a block diagram of the INTC.

**Figure 6.1 INTC Block Diagram**

## 6.2 Input/Output Pin

Table 6.1 lists the INTC pin configuration.

**Table 6.1 Pin Configuration**

| Name                            | Abbreviation                                                         | I/O | Description                                                                                             |
|---------------------------------|----------------------------------------------------------------------|-----|---------------------------------------------------------------------------------------------------------|
| Nonmaskable interrupt input pin | NMI                                                                  | I   | Nonmaskable interrupt request signal input                                                              |
| Interrupt input pins            | IRQ5 to IRQ0<br>$\overline{\text{IRL3}}$ to $\overline{\text{IRL0}}$ | I   | Interrupt request signal input<br>(Maskable by interrupt mask bits in SR)                               |
| Interrupt request output pin    | $\overline{\text{IRQOUT}}$                                           | O   | Output of signal that notifies external devices that an interrupt source or memory refresh has occurred |

## 6.3 Interrupt Sources

There are 4 types of interrupt sources: NMI, IRQ, IRL, and on-chip peripheral modules. The priority of each interrupt is indicated by a priority level value (16 to 0), with level 16 as the highest and level 1 as the lowest. When level 0 is set, the interrupt is masked and interrupt requests are ignored.

### 6.3.1 NMI Interrupts

The NMI interrupt has the highest priority level of 16. When the BLMSK bit of the interrupt control register (ICR1) is 1 or the BL bit of the status register (SR) is 0, NMI interrupts are accepted when the MAI bit of the ICR1 register is 0. NMI interrupts are edge-detected. In sleep or software standby mode, the interrupt is accepted regardless of the BL. The NMI edge select bit (NMIE) in the interrupt control register 0 (ICR0) is used to select either the rising or falling edge. When the NMIE bit of the ICR0 register is changed, the NMI interrupt is not detected for 20 cycles after changing the ICR0.NMIE to avoid a false detection of the NMI interrupt. NMI interrupt exception processing does not affect the interrupt mask level bits (I3 to I0) in the status register (SR).

When the BL bit is 1 and the BLMSK bit of the ICR1 register is set to 1, only NMI interrupts are accepted and the SPC register and SSR register are updated by the NMI interrupt handler, making it impossible to return to the original processing from exception processing initiated prior to the NMI. Use should therefore be restricted to cases where return is not necessary.

It is possible to wake the chip up from the software standby state with an NMI interrupt (except when the MAI bit of the ICR1 register is set to 1).

### 6.3.2 IRQ Interrupt

IRQ interrupts are input by priority from pins IRQ0 to IRQ5 with a level or an edge. The priority level can be set by priority setting registers C to D (IPRC to IPRD) in a range from levels 0 to 15.

When using edge-sensing for IRQ interrupts, clear the interrupt source by having software read 1 from the corresponding bit in IRR0, then write 0 to the bit.

When the ICR1 register is rewritten, IRQ interrupts may be mistakenly detected, depending on the pin states. To prevent this, rewrite the register while interrupts are masked, then release the mask after clearing the illegal interrupt by writing 0 to interrupt request register 0 (IRR0).

It is necessary for an edge input interrupt detection to input a pulse width more than two-cycle width by peripheral clock ( $P\phi$ ) basis.

In level detection, keep the level until the CPU accepts an interrupt and starts the interrupt processing.

The interrupt mask bits (I3 to I0) of the status register (SR) are not affected by IRQ interrupt processing.

Interrupts IRQ4 to IRQ0 can wake the chip up from the software standby state when the relevant interrupt level is higher than I3 to I0 in the SR register (but only when the RTC 32-kHz oscillator is used).

Notes: When the IRQ is used in edge sensitive, pay attention to the following:

1. If an IRQ edge is input immediately before the CPU enters standby mode (the period between the SLEEP instruction executed by the CPU to high level of STATUS0), an interrupt may not be detected. In this case, when an IRQ edge is input again after STATUS0 becomes high level, an interrupt is detected.
2. If an IRQ edge is input while the frequency is changed by the FRQCR STC bit (when the WDT is counting), an interrupt may not be detected. In this case, when an IRQ edge is input again after the WDT halts counting, an interrupt is detected.

6.3.3 IRL Interrupts

IRL interrupts are input by level at pins  $\overline{\text{IRL3}}$  to  $\overline{\text{IRL0}}$ . The priority level is the higher of those indicated by pins  $\overline{\text{IRL3}}$  to  $\overline{\text{IRL0}}$ . An  $\overline{\text{IRL3}}$  to  $\overline{\text{IRL0}}$  value of 0 (0000) indicates the highest-level interrupt request (interrupt priority level 15). A value of 15 (1111) indicates no interrupt request (interrupt priority level 0). Figure 6.2 shows an examples of an IRL interrupt connection. Table 6.2 shows  $\overline{\text{IRL}}$  pins and interrupt levels.

Figure 6.2 Example of IRL Interrupt Connection

Table 6.2  $\overline{\text{IRL3}}$  to  $\overline{\text{IRL0}}$  Pins and Interrupt Levels

| $\overline{\text{IRL3}}$ | $\overline{\text{IRL2}}$ | $\overline{\text{IRL1}}$ | $\overline{\text{IRL0}}$ | Interrupt Priority Level | Interrupt Request          |
|--------------------------|--------------------------|--------------------------|--------------------------|--------------------------|----------------------------|
| 0                        | 0                        | 0                        | 0                        | 15                       | Level 15 interrupt request |
| 0                        | 0                        | 0                        | 1                        | 14                       | Level 14 interrupt request |
| 0                        | 0                        | 1                        | 0                        | 13                       | Level 13 interrupt request |
| 0                        | 0                        | 1                        | 1                        | 12                       | Level 12 interrupt request |
| 0                        | 1                        | 0                        | 0                        | 11                       | Level 11 interrupt request |
| 0                        | 1                        | 0                        | 1                        | 10                       | Level 10 interrupt request |
| 0                        | 1                        | 1                        | 0                        | 9                        | Level 9 interrupt request  |
| 0                        | 1                        | 1                        | 1                        | 8                        | Level 8 interrupt request  |
| 1                        | 0                        | 0                        | 0                        | 7                        | Level 7 interrupt request  |
| 1                        | 0                        | 0                        | 1                        | 6                        | Level 6 interrupt request  |
| 1                        | 0                        | 1                        | 0                        | 5                        | Level 5 interrupt request  |
| 1                        | 0                        | 1                        | 1                        | 4                        | Level 4 interrupt request  |
| 1                        | 1                        | 0                        | 0                        | 3                        | Level 3 interrupt request  |
| 1                        | 1                        | 0                        | 1                        | 2                        | Level 2 interrupt request  |
| 1                        | 1                        | 1                        | 0                        | 1                        | Level 1 interrupt request  |
| 1                        | 1                        | 1                        | 1                        | 0                        | No interrupt request       |

A noise-cancellation feature is built in, and the IRL interrupt is not detected unless the levels sampled at every supporting module cycle remain unchanged for two consecutive cycles, so that no transient level on the  $\overline{\text{IRL}}$  pin change is detected. In the software standby mode, as the peripheral clock is stopped, noise cancellation is performed using the 32-kHz clock for the RTC instead. Therefore when the RTC is not used, interruption by means of IRL interrupts cannot be performed in software standby mode.

The priority level of the IRL interrupt must not be lowered unless the interrupt is accepted and the interrupt processing starts. If the level is not retained, correct operation is not guaranteed. However, the priority level can be changed to a higher one.

The interrupt mask bits (I3 to I0) in the status register (SR) are not affected by  $\overline{\text{IRL}}$  interrupt processing.

### 6.3.4 On-Chip Peripheral Module Interrupts

On-chip peripheral module interrupts are generated by the following nine modules:

- Timer unit (TMU)
- Realtime clock (RTC)
- Serial communication interface (SCI, SCIF)
- Bus state controller (BSC)
- Watchdog timer (WDT)
- Direct memory access controller (DMAC)
- A/D converter (ADC)
- User-debugging interface (H-UDI)

Not every interrupt source is assigned a different interrupt vector, but sources are reflected in the interrupt event registers (INTEVT and INTEVT2), so it is easy to identify sources by branching with the INTEVT or INTEVT2 register value as an offset.

The priority level (from 0 to 15) can be set for each module except for H-UDI by writing to the interrupt priority setting registers A, B and E (IPRA, IPRB and IPRE). The priority level of H-UDI interrupt is 15 (fixed).

The interrupt mask bits (I3 to I0) of the SR are not affected by the on-chip peripheral module interrupt processing.

TMU and RTC interrupts can restore the chip from the software standby state when the relevant interrupt level is higher than I3—I0 in the SR (but only when the RTC 32-kHz oscillator is used).

### 6.3.5 Interrupt Exception Processing and Priority

Tables 6.3 and 6.4 lists the codes for the interrupt event register (INTEVT and INTEVT2), and the order of interrupt priority. Each interrupt source is assigned unique code. The start address of the interrupt service routine is common to each interrupt source. This is why, for instance, the value of INTEVT or INTEVT2 is used as offset at the start of the interrupt service routine and branched to identify the interrupt source.

The order of priority of the on-chip peripheral module, IRQ, and PINT interrupts is set within the priority levels 0 to 15 at will by using the interrupt priority level set to registers A to E (IPRA to IPRE). The order of priority of the on-chip peripheral module, IRQ, and PINT interrupts is set to zero by RESET.

When the order of priorities for multiple interrupt sources are set to the same level and such interrupts are generated at the same time, they are processed according to the default order listed in tables 6.3 and 6.4.

### Table 6.3 Interrupt Exception Handling Sources and Priority (IRQ Mode)

| Interrupt Source |  | INTEVT Code<br>(INTEVT2 Code) | Interrupt<br>Priority<br>(Initial Value) | IPR (Bit<br>Numbers) | Priority<br>within IPR<br>Setting Unit | Default<br>Priority ## 6.4 Register Description

The INTC has the following registers. Refer to section 23, List of Registers, for more details of the addresses and access sizes.

- Interrupt control register 0 (ICR0)
- Interrupt control register 1 (ICR1)
- Interrupt priority level setting register A (IPRA)
- Interrupt priority level setting register B (IPRB)
- Interrupt priority level setting register C (IPRC)
- Interrupt priority level setting register D (IPRD)
- Interrupt priority level setting register E (IPRE)
- Interrupt request register 0 (IRR0)
- Interrupt request register 1 (IRR1)
- Interrupt request register 2 (IRR2)

### 6.4.1 Interrupt Priority Registers A to E (IPRA to IPRE)

The interrupt priority level setting registers A to E (IPRA to IPRE) are 16-bit read/write registers that set priority levels from 0 to 15 for on-chip peripheral module interrupts. These registers are initialized to H'0000 at power-on reset, manual reset, or in hardware standby mode, but is not initialized in standby mode.

Table 6.6 lists the relationship between the interrupt sources and the IPRA and IPRE bits.

**Table 6.6 Interrupt Request Sources and IPRA to IPRE**

| Register | Bits 15 to 12 | Bits 11 to 8 | Bits 7 to 4 | Bits 3 to 0 |
|----------|---------------|--------------|-------------|-------------|
| IPRA     | TMU0          | TMU1         | TMU2        | RTC         |
| IPRB     | WDT           | REF          | SCI0        | Reserved*   |
| IPRC     | IRQ3          | IRQ2         | IRQ1        | IRQ0        |
| IPRD     | Reserved*     | Reserved*    | IRQ5        | IRQ4        |
| IPRE     | DMAC          | Reserved*    | SCIF        | ADC         |

Note: \* These bits are always read as 0. The write value should be 0.

As shown in table 6.6, four sets of on-chip peripheral module, IRQ interrupts are assigned to each register. 4-bit groups (bits 15 to 12, bits 11 to 8, bits 7 to 4, and bits 3 to 0) are set with values from H'0 (0000) to H'F (1111). Setting H'0 means priority level 0 (masking is requested); H'F is priority level 15 (the highest level). A reset initializes IPRA to IPRE to H'0000.

H'0 should be set into bits corresponding to an unused interrupt.

## 6.4.2 Interrupt Control Register 0 (ICR0)

The interrupt control register 0 (ICR0) is a 16-bit register that sets the input signal detection mode of the external interrupt input pin NMI and indicates the input signal level to the NMI pin. This register is initialized to H'0000 at power-on reset or manual reset, but is not initialized in standby mode.

| Bit     | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                                                                                    |
|---------|----------|---------------|-----|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

This bit cannot be modified.<br><br>0: NMI input level is low<br>1: NMI input level is high                                                     |
| 14 to 9 | —        | 0             | R   | Reserved<br><br>These bits are always read as 0. The write value should always be 0.                                                                                                                                                                                           |
| 8       | NMIE     | 0             | R/W | NMI Edge Select<br><br>Selects whether the interrupt request signal is detected on the falling or rising edge of NMI input.<br><br>0: Interrupt request signal is detected on falling edge of NMI input<br>1: Interrupt request signal is detected on rising edge of NMI input |
| 7 to 0  | —        | 0             | R   | Reserved<br><br>These bits are always read as 0. The write value should always be 0.                                                                                                                                                                                           |

Note: \* When NMI input is high: 1; when NMI input is low: 0.

### 6.4.3 Interrupt Control Register 1 (ICR1)

The interrupt control register 1 (ICR1) is a 16-bit register that specifies the detection mode to external interrupt input pins, IRQ0 to IRQ5 individually: rising edge, falling edge, or low level.

| Bit | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

#### 6.4.4 Interrupt Request Register 0 (IRR0)

The interrupt request register 0 (IRR0) is an 8-bit register that indicates interrupt requests from external input pins IRQ0 to IRQ5.

When clearing IRQ5R to IRQ0R bit to 0, 0 should be written to the bit after the bit is set to 1 and the contents of 1 are read. Only 0 can be written to IRQ5R to IRQ0R.

| Bit | Bit Name | Initial Value | R/W | Description                                                          |
|-----|----------|---------------|-----|----------------------------------------------------------------------|
| 7   | —        | 0             | R   | Reserved                                                             |
| 6   | —        | 0             |     | These bits are always read as 0. The write value should always be 0. |

| Bit | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                                                                                                                           |

## 6.5 Operation

### 6.5.1 Interrupt Sequence

The sequence of interrupt operations is explained below. Figure 6.3 is a flowchart of the operations.

1. The interrupt request sources send interrupt request signals to the interrupt controller.
2. The interrupt controller selects the highest priority interrupt from the interrupt requests sent, following the priority levels set in interrupt priority registers A to E (IPRA to IPRE). Lower priority interrupts are held pending. If two of these interrupts have the same priority level or if multiple interrupts occur within a single module, the interrupt with the highest default priority or the highest priority within its IPR setting unit (as indicated in table 6.3 and table 6.4) is selected.
3. The priority level of the interrupt selected by the interrupt controller is compared with the interrupt mask bits (I3 to I0) in the status register (SR) of the CPU. If the request priority level is higher than the level in bits I3 to I0, the interrupt controller accepts the interrupt and sends an interrupt request signal to the CPU. When the interrupt controller receives an interrupt, a low level is output from the  $\overline{\text{IRQOUT}}$  pin.
4. Detection timing: The INTC operates in synchronization with the peripheral clock ( $P\phi$ ), and reports the interrupt request to the CPU. The CPU receives an interrupt at a break in instruction.
5. The interrupt source code is set in the interrupt event registers (INTEVT and INTEVT2).
6. The SR and PC are saved to SSR and SPC, respectively.
7. The BL, MD, and RB in SR are set to 1.
8. The CPU jumps to the start address of the interrupt handler (the sum of the value set in the vector base register (VBR) and H'00000600). This jump is not a delayed branch. The interrupt handler may branch with the INTEVT register value as its offset in order to identify the interrupt source. This enables it to branch to the processing routine for the individual interrupt source.

- Notes:
1. The interrupt mask bits (I3 to I0) in the SR are not changed by acceptance of an interrupt in this LSI.
  2.  $\overline{\text{IRQOUT}}$  outputs a low level until the interrupt request is cleared. However, if the interrupt source is masked by an interrupt mask bit, the  $\overline{\text{IRQOUT}}$  pin returns to the high level. The level is output without regard to the BL bit.
  3. The interrupt source flag should be cleared in the interrupt handler. The interrupt source flag should be cleared in the interrupt handler. To ensure that an interrupt request that should have been cleared is not inadvertently accepted again, read the source flag after it has been cleared, then wait for the interval shown in "Time for

priority decision and SR mask bit comparison" in table 6.7 before clearing the BL bit or executing an RTE instruction.

**Figure 6.3 Interrupt Operation Flowchart**

### 6.5.2 Multiple Interrupts

When multiple interrupts are used, the structure of the interrupt service routine should be as follows.

1. Branch to a specific interrupt handler corresponding to a code set in INTEVT and INTEVT2. The code in INTEVT and INTEVT2 can be used as a branch-offset for branching to the specific handler.
2. Clear the cause of the interrupt in each specific handler.
3. Save SSR and SPC to the memory.
4. Clear the BL bit in SR, and set the accepted interrupt level in the interrupt mask bits in SR.
5. Handle the interrupt.
6. Execute the RTE instruction.

When these procedures are followed in order, an interrupt of higher priority than the one being handled can be accepted after clearing BL in step 4.

## 6.6 Interrupt Response Time

The time from generation of an interrupt request until interrupt exception processing is performed and fetching of the first instruction of the exception handler is started (the interrupt response time) is shown in table 6.7. Figure 6.4 shows an example of pipeline operation when an IRL interrupt is accepted. When SR.BL is 1, interrupt exception processing is masked, and is kept waiting until completion of an instruction that clears BL to 0.

The response time is represented by the clock number of Iφ. Depending on the Pφ phase when an interrupt is occurred, one clock period of Pφ may vary from the contents of this table.

**Table 6.7 Interrupt Response Time**

| Item                                                                                                                                  | Number of States                                       |                                                                                         |                                                                                      |                                                                                                                          | Notes                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| Maximum case  | $10.5 + S$                                                                          | $15.5 + S$                                                                          | $20.5 + S$                                                                       | $10.5 + S^{*3}$<br>$16.5 + S^{*4}$                                                       | $\text{I}\phi: \text{B}\phi: \text{P}\phi = 4:1:1$ |

Icyc: Duration of one cycle of  $\text{I}\phi$ .

Bcyc: Duration of one cycle of  $\text{B}\phi$ .

Pcyc: Duration of one cycle of  $\text{P}\phi$ .

Notes: 1. S also includes the memory access wait time.

The processing requiring the maximum execution time is LDC.L @Rm+, SR. When the memory access is a cache-hit, this requires seven instruction execution cycles. When the external access is performed, the corresponding number of cycles must be added. There are also instructions that perform two external memory accesses; if the external memory access is slow, the number of instruction execution cycles will increase accordingly.

2. Edge detection.
3. Extended modules: TMU, RTC, SCI, WDT, REFC
4. Extended modules: DMAC, ADC, SCIF

**Figure 6.4 Example of Pipeline Operations when IRL Interrupt is Accepted**

# Section 7 User Break Controller

The UBC provides functions that simplify program debugging. Using this function, a self-monitor debugger can be easily prepared, and a program can be debugged using this LSI alone, without using an in-circuit emulator. Instruction fetches, data read/write, data size, data contents, address values, and the timing to stop execution at instruction fetch can be set to the UBC. The UBC block diagram is shown in figure 7.1.

## 7.1 Feature

The UBC has the following features:

- The following break comparison conditions can be set.  
Number of break channels: (channels A and B)  
Address: comparison bits are masked in units of 32 bits.  
One of the two address buses (the virtual address bus (LAB) and the internal address bus (IAB)) can be selected  
Data: only on channel B, 32-bit maskable  
One of two data buses (the virtual data bus (LDB) or the internal data bus (IDB)) can be selected.  
Bus master: CPU cycle or DMAC cycle  
Bus cycle: instruction fetch or data access  
Read/write  
Operand size: byte, word, or longword
- A user-designed user-break condition exception processing routine can be run.
- In an instruction fetch cycle, it can be selected that a break is set before or after an instruction is executed.
- The number of repeat times can be specified as a break condition. (It is only for channel B)
- Maximum repeat times for the break condition:  $2^{12} - 1$  times.
- Eight pairs of branch source/destination buffers.

**Figure 7.1 Block Diagram of User Break Controller**

## 7.2 Register Description

The UBC has the following registers. Refer to section 23, List of Registers, for more details of the addresses and access sizes.

- Break address register A (BARA)
- Break address mask register A (BAMRA)
- Break bus cycle register A (BBRA)
- Break address register B (BARB)
- Break address mask register B (BAMRB)
- Break bus cycle register B (BBRB)
- Break data register B (BDRB)
- Break data mask register B (BDMRB)
- Break control register (BRCR)
- Execution count break register (BETR)
- Branch source register (BRSR)
- Branch destination register (BRDR)
- Break ASID register A (BASRA)
- Break ASID register B (BASRB)

### 7.2.1 Break Address Register A (BARA)

BARA is a 32-bit read/write register. BARA specifies the address used as a break condition in channel A.

| Bit     | Bit Name      | Initial Value | R/W | Description                                                                                         |
|---------|---------------|---------------|-----|-----------------------------------------------------------------------------------------------------|
| 31 to 0 | BAA31 to BAA0 | 0             | R/W | Break Address<br>Stores the address on the LAB or IAB that specifies break conditions of channel A. |

## 7.2.2 Break Address Mask Register A (BAMRA)

BAMRA is a 32-bit read/write register. BAMRA specifies bits masked in the break address specified by BARA.

| Bit     | Bit Name             | Initial Value | R/W | Description                                                                                                                                                                                                                                                                                                                         |
|---------|----------------------|---------------|-----|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 0 | BAMA31 to 0<br>BAMA0 |               | R/W | Break Address Mask Bit<br><br>Specifies bits masked in the channel A break address bits specified by BARA (BAA31–BAA0).<br><br>0: Break address bit BAA <sub>n</sub> of channel A is included in the break condition<br><br>1: Break address bit BAA <sub>n</sub> of channel A is masked and is not included in the break condition |

Note: n = 31 to 0.

## 7.2.3 Break Bus Cycle Register A (BBRA)

Break bus cycle register A (BBRA) is a 16-bit read/write register, which specifies (1) CPU cycle or DMAC cycle, (2) instruction fetch or data access, (3) read or write, and (4) operand size in the break conditions of channel A.

| Bit     | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                                              |
|---------|----------|---------------|-----|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15 to 8 | —        | 0             | R   | Reserved<br><br>These bits are always read as 0. The write value should always be 0.                                                                                                                                                     |
| 7       | CDA1     | 0             | R/W | CPU Cycle/DMAC Cycle Select A                                                                                                                                                                                                            |

## 7.2.4 Break Address Register B (BARB)

BARB is a 32-bit read/write register. BARB specifies the address used as a break condition in channel B.

| Bit     | Bit Name      | Initial Value | R/W | Description                                                                                                    |
|---------|---------------|---------------|-----|----------------------------------------------------------------------------------------------------------------|
| 31 to 0 | BAB31 to BAB0 | 0             | R/W | <p>Break Address</p> <p>Stores the address of LAB or IAB that specifies the break conditions of channel B.</p> |

## 7.2.5 Break Address Mask Register B (BAMRB)

BAMRB is a 32-bit read/write register. BAMRB specifies bits masked in the break address specified by BARB.

| Bit     | Bit Name             | Initial Value | R/W | Description                                                                                                                                                                                                                                                                            |
|---------|----------------------|---------------|-----|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 0 | BAMB31 to 0<br>BAMB0 |               | R/W | Break Address Mask<br>Specifies bits masked in the channel B break address bits specified by BARB (BAB31 to BAB0).<br>0: Break address BABn of channel B is included in the break condition<br>1: Break address BABn of channel B is masked and is not included in the break condition |

Note: n 31 to 0

## 7.2.6 Break Data Register B (BDRB)

BDRB is a 32-bit read/write register.

| Bit     | Bit Name         | Initial Value | R/W | Description    |
|---------|------------------|---------------|-----|----------------|
| 31 to 0 | BDB31 to<br>BDB0 | 0             | R/W | Break Data Bit |

## 7.2.7 Break Data Mask Register B (BDMRB)

BDMRB is a 32-bit read/write register. BDMRB specifies bits masked in the break data specified by BDRB.

| Bit     | Bit Name           | Initial Value | R/W | Description                                                                                                                                                                   |
|---------|--------------------|---------------|-----|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 0 | BDMB31 to<br>BDMB0 | 0             | R/W | Break Data Mask<br>0: Break data BDBn of channel B is included in the break condition<br>1: Break data BDBn of channel B is masked and is not included in the break condition |

Notes: n = 31 to 0

1. Specify an operand size when including the value of the data bus in the break condition.
2. When a byte size is selected as a break condition, the break data must be set in bits 15 to 8 in BDRB for an even break address and bits 7 to 0 for an odd break address.

## 7.2.8 Break Bus Cycle Register B (BBRB)

Break bus cycle register B (BBRB) is a 16-bit read/write register, which specifies, (1) CPU cycle or DMAC cycle, (2) instruction fetch or data access, (3) read/write, and (4) operand size in the break conditions of channel B.

| Bit     | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                                                                                                                                                          |
|---------|----------|---------------|-----|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15 to 8 | —        | 0             | R   | Reserved<br>These bits are always read as 0. These bits are always read as 0.                                                                                                                                                                                                                                                                        |
| 7       | CDB1     | 0             | R/W | CPU Cycle/DMAC Cycle Select B                                                                                                                                                                                                                                                                                                                        |

## 7.2.9 Break Control Register (BRCR)

BRCR sets the following conditions:

1. Channels A and B are used in two independent channels condition or under the sequential condition.
2. A break is set before or after instruction execution.
3. A break is set by the number of execution times.
4. Determine whether to include data bus on channel B in comparison conditions.
5. Enable PC trace.
6. Enable the ASID check.

The break control register (BRCR) is a 32-bit read/write register that has break conditions match flags and bits for setting a variety of break conditions.

| Bit      | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                                                                                                   |

### 7.2.10 Execution Times Break Register (BETR)

When the execution-times break condition of channel B is enabled, this register specifies the number of execution times to make the break. The maximum number is  $2^{12} - 1$  times. Everytime the break condition is satisfied, BETR is decremented by 1. A break is issued when the break condition is satisfied after the BETR becomes H'0001.

### 7.2.11 Branch Source Register (BRSR)

BRSR is a 32-bit read register. BRSR stores the last fetched address before branch and the pointer (3 bits) which indicates the number of cycles from fetch to execution for the last executed instruction. BRSR has the flag bit that is set to 1 when branch occurs. This flag bit is cleared to 0, when BRSR is read and also initialized by power-on resets or manual resets. Other bits are not initialized by reset. Eight BRSR registers have queue structure and a stored register is shifted every branch.

Note: \* Undefined value

## 7.2.12 Branch Destination Register (BRDR)

BRDR is a 32-bit read register. BRDR stores the branch destination fetch address. BRDR has the flag bit that is set to 1 when branch occurs. This flag bit is cleared to 0, when BRDR is read and also initialized by power-on resets or manual resets. Other bits are not initialized by resets. Eight BRDR registers have queue structure and a stored register is shifted every branch.

Note: \* Undefined value

## 7.2.13 Break ASID Register A (BASRA)

Break ASID register A (BASRA) is an 8-bit read/write register that specifies the ASID that serves as the break condition for channel A. It is not initialized by resets. It is located in CCN.

| Bit    | Bit Name       | Initial Value | R/W | Description                                                                                      |
|--------|----------------|---------------|-----|--------------------------------------------------------------------------------------------------|
| 7 to 0 | BASA7 to BASA0 | *             | R/W | Break ASID<br><br>These bits store the ASID (bits 7 to 0) that is the channel A break condition. |

Note: \* Undefined value

## 7.2.14 Break ASID Register B (BASRB)

Break ASID register B (BASRB) is an 8-bit read/write register that specifies the ASID that serves as the break condition for channel B. It is not initialized by resets. It is located in CCN.

| Bit    | Bit Name       | Initial Value | R/W | Description                                                                                  |
|--------|----------------|---------------|-----|----------------------------------------------------------------------------------------------|
| 7 to 0 | BASB7 to BASB0 | *             | R/W | Break ASID<br>These bits store the ASID (bits 7 to 0) that is the channel B break condition. |

Note: \* Undefined value

## 7.3 Operation

### 7.3.1 Flow of the User Break Operation

The flow from setting of break conditions to user break exception processing is described below:

1. The break addresses and the corresponding ASIDs are loaded in the BARA, BARB, BASRA and BASRB. The masked addresses are set in the BAMRA and BAMRB. The break data is set in the BDRB. The masked data is set in the BDMRB. The breaking bus conditions are set in the BBRA and BBRB. Three groups of the BBRA and BBRB (CPU cycle/DMAC cycle select, instruction fetch/data access select, and read/write select) are each set. No user break will be generated if even one of these groups is set with 00. The respective conditions are set in the bits of the BRRCR.
2. When the break conditions are satisfied, the UBC sends a user break request to the interrupt controller. The break type will be sent to CPU indicating the instruction fetch, pre/post instruction break, or data access break. When conditions match up, the CPU condition match flags (SCMFCA and SCMFCEB) and DMAC condition match flags (SCMFDA and SCMFDEB) for the respective channels are set.
3. The appropriate condition match flags (SCMFCA, SCMFDA, SCMFCEB, and SCMFDEB) can be used to check if the set conditions match or not. The matching of the conditions sets flags, but they are not reset. 0 must first be written to them before they can be used again.
4. There is a chance that the data access break and its following instruction fetch break occur around the same time, there will be only one break request to the CPU, but these two break channel match flags could be both set.

### 7.3.2 Break on Instruction Fetch Cycle

1. When CPU/instruction fetch/read/word or longword is set in the break bus cycle registers (BBRA/BBRB), the break condition becomes the CPU instruction fetch cycle. Whether it then breaks before or after the execution of the instruction can then be selected with the PCBA/PCBB bits of the break control register (BRCR) for the appropriate channel.
2. An instruction set for a break before execution breaks when it is confirmed that the instruction has been fetched and will be executed. This means this feature cannot be used on instructions fetched by overrun (instructions fetched at a branch or during an interrupt transition, but not to be executed). When this kind of break is set for the delay slot of a delay branch instruction, the break is generated prior to execution of the instruction that then first accepts the break. Meanwhile, the break set for pre-instruction-break on delay slot instruction and post-instruction-break on SLEEP instruction are also prohibited.
3. When the condition is specified to be occurred after execution, the instruction set with the break condition is executed and then the break is generated prior to the execution of the next instruction. As with pre-execution breaks, this cannot be used with overrun fetch instructions. When this kind of break is set for a delay branch instruction, the break is generated at the instruction that then first accepts the break.
4. When an instruction fetch cycle is set for channel B, break data register B (BDRB) is ignored. There is thus no need to set break data for the break of the instruction fetch cycle.

### 7.3.3 Break by Data Access Cycle

1. The memory cycles in which CPU data access breaks occur are from instructions.
2. The relationship between the data access cycle address and the comparison condition for operand size are listed in table 7.1:

**Table 7.1 Data Access Cycle Addresses and Operand Size Comparison Conditions**

| Access Size | Address Compared                                                         |
|-------------|--------------------------------------------------------------------------|
| Longword    | Compares break address register bits 31 to 2 to address bus bits 31 to 2 |
| Word        | Compares break address register bits 31 to 1 to address bus bits 31 to 1 |
| Byte        | Compares break address register bits 31 to 0 to address bus bits 31 to 0 |

This means that when address H'00001003 is set without specifying the size condition, for example, the bus cycle in which the break condition is satisfied is as follows (where other conditions are met).

Longword access at H'00001000

Word access at H'00001002

Byte access at H'00001003

3. When the data value is included in the break conditions on B channel:

When the data value is included in the break conditions, either longword, word, or byte is specified as the operand size of the break bus cycle registers (BBRA and BBRB). When data values are included in break conditions, a break is generated when the address conditions and data conditions both match. To specify byte data for this case, set the same data in two bytes at bits 15–8 and bits 7–0 of the break data register B (BDRB) and break data mask register B (BDMRB). When word or byte is set, bits 31–16 of BDRB and BDMRB are ignored.

4. When the DMAC data access is included in the break condition:

When the address is included in the break condition on DMAC data access, the operand size of the break bus cycle registers (BBRA and BBRB) should be byte, word or no specified operand size. When the data value is included, select either byte or word.

### 7.3.4 Sequential Break

1. By specifying SEQ in BRCCR is set to 1, the sequential break is issued when channel B break condition matches after channel A break condition matches. A user break is ignored even if channel B break condition matches before channel A break condition matches. When channels A and B condition match at the same time, the sequential break is not issued.
2. In sequential break specification, logical or internal bus can be selected and the execution times break condition can be also specified. For example, when the execution times break condition is specified, the break condition is satisfied at channel B condition match with BETR = H'0001 after channel A condition match.

### 7.3.5 Value of Saved Program Counter

The PC when a break occurs is saved to the SPC in user breaks. The PC value saved is as follows depending on the type of break.

1. When instruction fetch (before instruction execution) is specified as a break condition:  
The value of the program counter (PC) saved is the address of the instruction that matches the break condition. The fetched instruction is not executed, and a break occurs before it.
2. When instruction fetch (after instruction execution) is specified as a break condition:  
The PC value saved is the address of the instruction to be executed following the instruction in which the break condition matches. The fetched instruction is executed, and a break occurs before the execution of the next instruction.
3. When data access (address only) is specified as a break condition:  
The PC value is the address of the instruction to be executed following the instruction that matched the break condition. The instruction that matched the condition is executed and the break occurs before the next instruction is executed.
4. When data access (address + data) is specified as a break condition:

The PC value is the start address of the instruction that follows the instruction already executed when break processing started up. When a data value is added to the break conditions, the place where the break will occur cannot be specified exactly. The break will occur before the execution of an instruction fetched around the data access where the break occurred.

### 7.3.6 PC Trace

1. Setting PCTE in BRCCR to 1 enables PC traces. When branch (branch instruction, repeat, and interrupt) is generated, the address from which the branch source address can be calculated and the branch destination address are stored in BRSR and BRDR, respectively. The branch address and the pointer, which corresponds to the branch, are included in BRSR.
2. The branch address before branch occurs can be calculated from the address and the pointer stored in BRSR. The expression from BSA (the address in BRSR), PID (the pointer in BRSR), and IA (the instruction address before branch occurs) is as follows:  $IA = BSA - 2 * PID$ .

Notes are needed when an interrupt (a branch) is issued before the branch destination instruction is executed. In case of the next figure, the instruction “Exec” executed immediately before branch is calculated by  $IA = BSA - 2 * PID$ . However, when branch “branch” has delay slot and the destination address is  $4n + 2$  address, the address “Dest” which is specified by branch instruction is stored in BRSR ( $Dest = BSA$ ). Therefore, as  $IA = BSA - 2 * PID$  is not applied to this case, this PID is invalid. The case where BSA is  $4n + 2$  boundary is applied only to this case and then some cases are classified as follows:

Exec: branch Dest

Dest: instr (not executed)  
interrupt

Int: interrupt routine

If the PID value is odd, instruction buffer indicates PID+2 buffer. However, these expressions in this table are accounted for it. Therefore, the true branch source address is calculated with BSA and PID values stored in BRSR.

3. The branch address before branch occurrence, IA, has different values due to some kinds of branch.
  - a. Branch instruction  
The branch instruction address
  - b. Interrupt  
The last instruction executed before interrupt  
The top address of interrupt routine is stored in BRDR.
4. BRSR and BRDR have eight pairs of queue structures. The top of queues is read first when the address stored in the PC trace register is read. BRSR and BRDR share the read pointer. Read BRSR and BRDR in order, the queue only shifts after BRDR is read. When reading BRDR, longword access should be used. Also, the PC trace has a trace pointer, which initially points to the bottom of the queues. The first pair of branch addresses will be stored at the bottom of

the queues, then push up when next pairs come into the queues. The trace pointer will points to the next branch address to be executed, unless it got push out of the queues. When the branch address has been executed, the trace pointer will shift down to next pair of addresses, until it reaches the bottom of the queues. After switching the PCTE bit (in BR CR) off and on, the values in the queues are invalid. The read pointer stay at the position before PCTE is switched, but the trace pointer restart at the bottom of the queues.

### 7.3.7 Usage Examples

#### Break Condition Specified to a CPU Instruction Fetch Cycle

##### 1. Register specifications

BARA = H'00000404, BAMRA = H'00000000, BBRA = H'0054, BARB = H'00008010, BAMRB = H'00000006, BBRB = H'0054, BDRB = H'00000000, BDMRB = H'00000000, BRRCR = H'00300400

Specified conditions: Channel A/channel B independent mode

- Channel A

Address: H'00000404, Address mask: H'00000000

Bus cycle: CPU/instruction fetch (after instruction execution)/read (operand size is not included in the condition)

No ASID check is included

- Channel B

Address: H'00008010, Address mask: H'00000006

Data: H'00000000, Data mask: H'00000000

Bus cycle: CPU/instruction fetch (before instruction execution)/read (operand size is not included in the condition)

No ASID check is included

A user break occurs after an instruction of address H'00000404 is executed or before instructions of addresses H'00008010 to H'00008016 are executed.

##### 2. Register specifications

BARA = H'00037226, BAMRA = H'00000000, BBRA = H'0056, BARB = H'0003722E, BAMRB = H'00000000, BBRB = H'0056, BDRB = H'00000000, BDMRB = H'00000000, BRRCR = H'00000008, BASRA = H'80, BASRB = H'70

Specified conditions: Channel A/channel B sequence mode

- Channel A

Address: H'00037226, Address mask: H'00000000, ASID = H'80

Bus cycle: CPU/instruction fetch (before instruction execution)/read/word

- Channel B

Address: H'0003722E, Address mask: H'00000000, ASID = H'70

Data: H'00000000, Data mask: H'00000000

Bus cycle: CPU/instruction fetch (before instruction execution)/read/word

An instruction with ASID = H'80 and address H'00037226 is executed, and a user break occurs before an instruction with ASID = H'70 and address H'0003722E is executed.

### 3. Register specifications

BARA = H'00027128, BAMRA = H'00000000, BBRA = H'005A, BARB = H'00031415, BAMRB = H'00000000, BBRB = H'0054, BDRB = H'00000000, BDMRB = H'00000000, BRCR = H'00300000

Specified conditions: Channel A/channel B independent mode

- Channel A

Address: H'00027128, Address mask: H'00000000

Bus cycle: CPU/instruction fetch (before instruction execution)/write/word

No ASID check is included

- Channel B

Address: H'00031415, Address mask: H'00000000

Data: H'00000000, Data mask: H'00000000

Bus cycle: CPU/instruction fetch (before instruction execution)/read (operand size is not included in the condition)

No ASID check is included

On channel A, no user break occurs since instruction fetch is not a write cycle. On channel B, no user break occurs since instruction fetch is performed for an even address.

### 4. Register specifications

BARA = H'00037226, BAMRA = H'00000000, BBRA = H'005A, BARB = H'0003722E, BAMRB = H'00000000, BBRB = H'0056, BDRB = H'00000000, BDMRB = H'00000000, BRCR = H'00000008, BASRA = H'80, BASRB = H'70

Specified conditions: Channel A/channel B sequence mode

- Channel A

Address: H'00037226, Address mask: H'00000000, ASID: H'80

Bus cycle: CPU/instruction fetch (before instruction execution)/write/word

- Channel B

Address: H'0003722E, Address mask: H'00000000, ASID: H'70

Data: H'00000000, Data mask: H'00000000

Bus cycle: CPU/instruction fetch (before instruction execution)/read/word

Since instruction fetch is not a write cycle on channel A, a sequence condition does not match. Therefore, no user break occurs.

### 5. Register specifications

BARA = H'00000500, BAMRA = H'00000000, BBRA = H'0057, BARB = H'00001000, BAMRB = H'00000000, BBRB = H'0057, BDRB = H'00000000, BDMRB = H'00000000, BRCR = H'00300001, BETR = H'0005

Specified conditions: Channel A/channel B independent mode

- Channel A

Address: H'00000500, Address mask: H'00000000

Bus cycle: CPU/instruction fetch (before instruction execution)/read/longword

- Channel B

Address: H'00001000, Address mask: H'00000000

Data: H'00000000, Data mask: H'00000000

Bus cycle: CPU/instruction fetch (before instruction execution)/read/longword

The number of execution-times break enable (5 times)

On channel A, a user break occurs before an instruction of address H'00000500 is executed.

On channel B, a user break occurs before the fifth instruction execution after instructions of address H'00001000 are executed four times.

## 6. Register specifications

BARA = H'00008404, BAMRA = H'00000FFF, BBRA = H'0054, BARB = H'00008010, BAMRB = H'00000006, BBRB = H'0054, BDRB = H'00000000, BDMRB = H'00000000, BR CR = H'00000400, BASRA = H'80, BASRB = H'70

Specified conditions: Channel A/channel B independent mode

- Channel A

Address: H'00008404, Address mask: H'00000FFF, ASID: H'80

Bus cycle: CPU/instruction fetch (after instruction execution)/read (operand size is not included in the condition)

- Channel B

Address: H'00008010, Address mask: H'00000006, ASID: H'70

Data: H'00000000, Data mask: H'00000000

Bus cycle: CPU/instruction fetch (before instruction execution)/read (operand size is not included in the condition)

A user break occurs after an instruction with ASID = H'80 and address H'00008000 to H'00008FFE is executed or before instructions with ASID = H'70 and addresses H'00008010 to H'00008016 are executed.

## Break Condition Specified to a CPU Data Access Cycle

### 1. Register specifications

BARA = H'00123456, BAMRA = H'00000000, BBRA = H'0064, BARB = H'000ABCDE, BAMRB = H'000000FF, BBRB = H'006A, BDRB = H'0000A512, BDMRB = H'00000000, BR CR = H'00000080, BASRA = H'80, BASRB = H'70

Specified conditions: Channel A/channel B independent mode

- Channel A

Address: H'00123456, Address mask: H'00000000

Bus cycle: CPU/data access/read (operand size is not included in the condition)

- Channel B

Address: H'000ABCDE, Address mask: H'000000FF, ASID: H'70

Data: H'0000A512, Data mask: H'00000000

Bus cycle: CPU/data access/write/word

On channel A, a user break occurs with ASID = H'80 during longword read to address H'00123454, word read to address H'00123456, or byte read to address H'00123456. On channel B, a user break occurs with ASID = H'70 when word H'A512 is written in addresses H'000ABC00 to H'000ABCFE.

## Break Condition Specified to a DMAC Data Access Cycle

### 1. Register specifications:

BARA = H'00314156, BAMRA = H'00000000, BBRA = H'0094, BARB = H'00055555, BAMRB = H'00000000, BBRB = H'00A9, BDRB = H'00000078, BDMRB = H'0000000F, BRCCR = H'00000080, BASRA = H'80, BASRB = H'70

Specified conditions: Channel A/channel B independent mode

- Channel A

Address: H'00314156, Address mask: H'00000000, ASID: H'80

Bus cycle: DMAC/instruction fetch/read (operand size is not included in the condition)

- Channel B

Address: H'00055555, Address mask: H'00000000, ASID: H'70

Data: H'00000078, Data mask: H'0000000F

Bus cycle: DMAC/data access/write/byte

On channel A, no user break occurs since instruction fetch is not performed in DMAC cycles. On channel B, a user break occurs with ASID = H'70 when the DMAC writes byte H'7\* in address H'00055555.

## 7.4 Usage Note

1. Only CPU can read/write UBC registers.
2. UBC cannot monitor CPU and DMAC access in the same channel.
3. Notes in specification of sequential break are described below:
  - A. A condition match occurs when B-channel match occurs in a bus cycle after an A-channel match occurs in another bus cycle in sequential break setting. Therefore, no condition match occurs even if a bus cycle, in which an A-channel match and a channel B match occur simultaneously, is set.
  - B. Since the CPU has a pipeline configuration, the pipeline determines the order of an instruction fetch cycle and a memory cycle. Therefore, when a channel condition matches in the order of bus cycles, a sequential condition is satisfied.
  - C. When the bus cycle condition for channel A is specified as a break before execution (PCBA = 0 in BRCCR) and an instruction fetch cycle (in BBRA), the attention is as follows. A break is issued and condition match flags in BRCCR are set to 1, when the bus cycle conditions both for channels A and B match simultaneously.

4. The change of a UBC register value is executed in MA (memory access) stage. Therefore, even if the break condition matches in the instruction fetch address following the instruction in which the pre-execution break is specified as the break condition, no break occurs. In order to know the timing UBC register is changed, read the last written register. Instructions after then are valid for the newly written register value.
5. The branch instruction should not be executed as soon as PC trace register BRSR and BRDR are read.
6. When PC breaks and TLB exceptions or errors occur in the same instruction. The priority is as follows:
  - A. Break and instruction fetch exceptions: Instruction fetch exception occurs first.
  - B. Break before execution and operand exception: Break before execution occurs first.
  - C. Break after execution and operand exception: Operand exception occurs first.

## Section 8 Bus State Controller (BSC)

The bus state controller (BSC) divides physical address space and output control signals for various types of memory and bus interface specifications. BSC functions enable this LSI to link directly with DRAM, synchronous DRAM, SRAM, ROM, and other memory storage devices without an external circuit. The BSC also allows direct connection to PCMCIA interfaces, simplifying system design and allowing high-speed data transfers in a compact system.

Figure 8.1 shows the block diagram of the BSC.

### 8.1 Feature

The BSC has the following features:

- Physical address space is divided into six areas
  - A maximum 64 Mbytes for each of the six areas, 0, 2 to 6
  - Area bus width can be selected by register (area 0 is set by external pin)
  - Wait states can be inserted using the  $\overline{\text{WAIT}}$  pin
  - Wait state insertion can be controlled through software. Register settings can be used to specify the insertion of 1 to 10 cycles independently for each area (1 to 38 cycles for areas 5 and 6 and the PCMCIA interface only)
  - The type of memory connected can be specified for each area, and control signals are output for direct memory connection
  - Wait cycles are automatically inserted to avoid data bus conflict for continuous memory accesses to different areas or writes directly following reads of the same area
- Direct interface to synchronous DRAM (except when clock ratio becomes  $I\phi:B\phi = 1:1$ )
  - Multiplexes row/column addresses according to synchronous DRAM capacity
  - Supports burst operation
  - Supports bank active mode
  - Has both auto-refresh and self-refresh functions
  - Controls timing of synchronous DRAM direct-connection control signals according to register setting
- Burst ROM interface
  - Insertion of wait states controllable through software
  - Register setting control of burst transfers
- PCMCIA direct-connection interface
  - Insertion of wait states controllable through software
  - Bus sizing function for I/O bus width (only in the little endian mode)

- Refresh function
  - Refresh cycles will be automatically maintained in the sleep mode even after the external bus frequency is reduced to 1/4 of its normal operating frequency
- The refresh counter can be used as an interval timer
  - Outputs an interrupt request signal using the compare-matching function
  - Outputs an interrupt request signal when the refresh counter overflows

**Figure 8.1 BSC Functional Block Diagram**

## 8.2 Input/Output Pin

Table 8.1 lists the BSC pin configuration.

**Table 8.1 Pin Configuration**

| Pin Name              | Signal                                                  | I/O | Description                                                                                                                                                                                                  |
|-----------------------|---------------------------------------------------------|-----|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Address bus           | A25 to A0                                               | O   | Address output                                                                                                                                                                                               |
| Data bus              | D15 to D0                                               | I/O | Data I/O                                                                                                                                                                                                     |
|                       | D31 to D16                                              | I/O | When 32-bit bus width, data I/O                                                                                                                                                                              |
| Bus cycle start       | $\overline{BS}$                                         | O   | Shows start of bus cycle. During burst transfers, asserts every data cycle.                                                                                                                                  |
| Chip select 0, 2 to 4 | $\overline{CS0}$ , $\overline{CS2}$ to $\overline{CS4}$ | O   | Chip select signal to indicate area being accessed.                                                                                                                                                          |
| Chip select 5, 6      | $\overline{CS5/CE1A}$ ,<br>$\overline{CS6/CE1B}$        | O   | Chip select signal to indicate area being accessed. $\overline{CS5/CE1A}$ and $\overline{CS6/CE1B}$ can also be used as $\overline{CE1A}$ and $\overline{CE1B}$ of PCMCIA.                                   |
| PCMCIA card select    | $\overline{CE2A}$ , $\overline{CE2B}$                   | O   | When PCMCIA is used, CE2A and CE2B                                                                                                                                                                           |
| Read/write            | $\overline{RD/WR}$                                      | O   | Data bus direction indicator signal. Synchronous DRAM write indicator signal.                                                                                                                                |
| Row address strobe L  | $\overline{RASL}$                                       | O   | When synchronous DRAM is used, RASL for lower 32-Mbyte address.                                                                                                                                              |
| Row address strobe U  | $\overline{RASU}$                                       | O   | When synchronous DRAM is used, RASU for upper 32-Mbyte address.                                                                                                                                              |
| Column address strobe | $\overline{CASL}$                                       | O   | When synchronous DRAM is used, CASL signal for lower 32-Mbyte address.                                                                                                                                       |
| Column address strobe | $\overline{CASU}$                                       | O   | When synchronous DRAM is used, CASU signal for upper 32-Mbyte address.                                                                                                                                       |
| Data enable 0         | $\overline{WE0/DQMLL}$                                  | O   | When memory other than synchronous DRAM is used, selects D7 to D0 write strobe signal. When synchronous DRAM is used, selects D7 to D0.                                                                      |
| Data enable 1         | $\overline{WE1/DQMLU/WE}$                               | O   | When memory other than synchronous DRAM is used, selects D15 to D8 write strobe signal. When synchronous DRAM is used, selects D15 to D8. When PCMCIA is used, strobe signal that indicates the write cycle. |
| Data enable 2         | $\overline{WE2/DQMUL/ICIORD}$                           | O   | When memory other than synchronous DRAM is used, selects D23 to D16 write strobe signal. When synchronous DRAM is used, selects D23 to D16. When PCMCIA is used, strobe signal indicating I/O read.          |

| Pin Name                   | Signal                                                | I/O | Description                                                                                                                                                                                          |
|----------------------------|-------------------------------------------------------|-----|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Data enable 3              | $\overline{\text{WE3/DQM0U}}/\overline{\text{ICIOR}}$ | O   | When memory other than synchronous DRAM is used, selects D31 to D24 write strobe signal. When synchronous DRAM is used, selects D31 to D24. When PCMCIA is used, strobe signal indicating I/O write. |
| Read                       | $\overline{\text{RD}}$                                | O   | Strobe signal indicating read cycle                                                                                                                                                                  |

| Bus release acknowledgment | $\overline{\text{BACK}}$                              | O   | Bus release acknowledge signal                                                                                                                                                                       |

### 8.3 Area Overview

**Space Allocation:** In the architecture of this LSI, both logical spaces and physical spaces have 32-bit address spaces. The logical space is divided into five areas by the value of the upper bits of the address. The physical space is divided into eight areas.

Logical space can be allocated at physical spaces using a memory management unit (MMU). For details, refer to section 3, Memory Management Unit, which describes area allocation for physical spaces.

As listed in table 8.2, this LSI can be connected directly to six areas of memory/PCMCIA interface, and it outputs chip select signals ( $\overline{\text{CS0}}$ ,  $\overline{\text{CS2}}$  to  $\overline{\text{CS6}}$ ,  $\overline{\text{CE2A}}$ ,  $\overline{\text{CE2B}}$ ) for each of them.  $\overline{\text{CS0}}$  is asserted during area 0 access;  $\overline{\text{CS6}}$  is asserted during area 6 access. When PCMCIA interface is selected in area 5 or 6, in addition to  $\overline{\text{CS5/CS6}}$ ,  $\overline{\text{CE2A/CE2B}}$  are asserted for the corresponding bytes accessed.

Note: For logical address spaces P0 and P3, when the memory management unit (MMU) is on, it can optionally generate a physical address for the logical address. It can be applied when the MMU is off and when the MMU is on and each physical address for the logical address is equal except for upper three bits.

|                 |                                                      | H'18000000 + H'20000000 × n to<br>H'1BFFFFFF + H'20000000 × n | Shadow    |                            |
| 7 <sup>*7</sup> | Reserved area                                        | H'1C000000 + H'20000000 × n<br>to H'1FFFFFFF + H'20000000 × n |           | n: 0 to 7                  |

- Notes:
1. Memory with interface such as SRAM or ROM.
  2. Use external pin to specify memory bus width.
  3. Use register to specify memory bus width.
  4. With synchronous DRAM interfaces, bus width must be 16 or 32 bits.
  5. With synchronous DRAM interfaces, bus width must be 16 or 32 bits.
  6. With PCMCIA interface, bus width must be 8 or 16 bits.
  7. Do not access the reserved area. If the reserved area is accessed, the correct operation cannot be guaranteed.
  8. When the control register in area 1 is not used for address translation by the MMU, set the top three bits of the logical address to 101 to allocate in the P2 space.

| Area 4: H'10000000 | Ordinary memory                      |                                                                                                                                           |
| Area 5: H'14000000 | Ordinary memory/<br>burst ROM/PCMCIA |                                                                                                                                           |
| Area 6: H'18000000 | Ordinary memory/<br>burst ROM/PCMCIA |                                                                                                                                           |

**Figure 8.3 Physical Space Allocation**

**Memory Bus Width:** The memory bus width in this LSI can be set for each area. In area 0, an external pin can be used to select byte (8 bits), word (16 bits), or longword (32 bits) on power-on reset. The correspondence between the external pins (MD4 and MD3) and memory size is listed in table below.

**Table 8.3 Correspondence between External Pins (MD4 and MD3) and Memory Size**

| MD4 | MD3 | Memory Size                   |
|-----|-----|-------------------------------|
| 0   | 0   | Reserved (Setting prohibited) |
| 0   | 1   | 8 bits                        |
| 1   | 0   | 16 bits                       |
| 1   | 1   | 32 bits                       |

For areas 2 to 6, byte, word, and longword may be chosen for the bus width using bus control register 2 (BCR2) whenever ordinary memory, ROM, or burst ROM are used. When the synchronous DRAM interface is used, word or longword can be chosen as the bus width.

When the PCMCIA interface is used, set the bus width to byte or word. When synchronous DRAM is connected to both area 2 and area 3, set the same bus width for areas 2 and 3. When using port A or B, set a bus width of 8 or 16 bits for all areas. For more information, see section 8.4.2, Bus Control Register 2 (BCR2).

**Shadow Space:** Areas 0, 2 to 6 are decoded by physical addresses A28 to A26, which correspond to areas 000 to 110. Address bits 31 to 29 are ignored. This means that the range of area 0 addresses, for example, is H'00000000 to H'03FFFFFF, and its corresponding shadow space is the address space obtained by adding to it  $H'20000000 \times n$  ( $n = 1$  to 6). The address range for area 7, which is on-chip I/O space, is H'1C000000 to H'1FFFFFFF. The address space  $H'1C000000 + H'20000000 \times n - H'1FFFFFFF + H'20000000 \times n$  ( $n = 0$  to 7) corresponding to the area 7 shadow space is reserved, so do not use it.

### 8.3.1 PCMCIA Support

This LSI supports PCMCIA standard interface specifications in physical space areas 5 and 6 (except for WP).

The interfaces supported are basically the "IC memory card interface" and "I/O card interface" stipulated in JEIDA Specifications Ver. 4.2 (PCMCIA2.1).

**Table 8.4 PCMCIA Interface Characteristics**

| Item               | Feature                                                                                                                                         |

Note: \* This LSI does not support WP.

## 8.4 Register Description

The BSC has 11 registers. The synchronous DRAM also has a built-in synchronous DRAM mode register. These registers control direct connection interfaces to memory, wait states and refreshes.

Refer to section 23, List of Registers, for more details of the addresses and access sizes.

- Bus control register 1 (BCR1)
- Bus control register 2 (BCR2)
- Wait state control register 1 (WCR1)
- Wait state control register 2 (WCR2)
- Individual memory control register (MCR)
- PCMCIA control register (PCR)
- Synchronous DRAM mode register (SDMR)
- Refresh timer control/status register (RTCSR)
- Refresh timer counter (RTCNT)
- Refresh time constant register (RTCOR)
- Refresh count register (RFCR)

### 8.4.1 Bus Control Register 1 (BCR1)

Bus control register 1 (BCR1) is a 16-bit read/write register that sets the functions and bus cycle state for each area. It is initialized to H'0000 by a power-on reset, but is not initialized by a manual reset or by standby mode. Do not access external memory outside area 0 until BCR1 register initialization is complete.

| Bit | Bit Name | Initial Value | R/W | Description                                                                                                                                                                             |

Notes: 1. Samples the value of the external pin (MD5) designating endian at power-on reset.  
2. When selecting this mode, set the same bus width for area 2 and 3.  
3. Do not access to the SRAM when the clock ratio is  $I\phi : B\phi = 1:1$ .

## 8.4.2 Bus Control Register 2 (BCR2)

The bus control register 2 (BCR2) is a 16-bit read/write register that selects the bus-size width and 8-bit port of each area. It is initialized to H'3FF0 by a power-on reset, but is not initialized by a manual reset or by standby mode. Do not access external memory outside area 0 until BCR2 register initialization is complete.

| Bit | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

### 8.4.3 Wait State Control Register 1 (WCR1)

Wait state control register 1 (WCR1) is a 16-bit read/write register that specifies the number of idle (wait) state cycles inserted for each area. For some memories, the drive of the data bus may not be turned off quickly even when the read signal from the external device is turned off. This can result in conflicts between data buses when consecutive memory accesses are to different memories or when a write immediately follows a memory read. This LSI automatically inserts idle states equal to the number set in WCR1 in those cases.

WCR1 is initialized to H'3FF3 by a power-on reset. It is not initialized by a manual reset or by standby mode.

## 8.4.4 Wait State Control Register 2 (WCR2)

Wait state control register 2 (WCR2) is a 16-bit read/write register that specifies the number of wait state cycles inserted for each area. It also specifies the pitch of data access for burst memory accesses. This allows direct connection of even low-speed memories without an external circuit.

#### 8.4.5 Individual Memory Control Register (MCR)

The individual memory control register (MCR) is a 16-bit read/write register that specifies  $\overline{\text{RAS}}$  and  $\overline{\text{CAS}}$  timing and burst control for synchronous DRAM (areas 2 and 3), specifies address multiplexing, and controls refresh. This enables direct connection of synchronous DRAM without external circuits.

The MCR is initialized to H'0000 by power-on resets, but is not initialized by manual resets or standby mode. The bits TPC1, TPC0, RCD1, RCD0, TRWL1, TRWL0, TRAS1, TRAS0, RASD and AMX3 to AMX0 are written to at the initialization after a power-on reset and are not then modified again. When RFSH and RMODE are written to, write the same values to the other bits. When using synchronous DRAM, do not access areas 2 and 3 until this register is initialized.

| Bit              | Bit Name                                | Initial Value                     | R/W | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                  |                                         |                                   |             |         |          |              |         |          |              |          |          |              |          |           |

### 8.4.6 PCMCIA Control Register (PCR)

The PCMCIA control register (PCR) is a 16-bit read/write register that specifies the timing for the assertion or negation of the OE and WE signals for the PCMCIA interface connected to areas 5 and 6. The width for assertion of the OE and WE signals is set by the wait control bit in the WCR2 register.

### 8.4.7 Synchronous DRAM Mode Register (SDMR)

The synchronous DRAM mode register (SDMR) is written to via the synchronous DRAM address bus and is an 8-bit write-only register. It sets synchronous DRAM mode for areas 2 and 3. SDMR must be set before synchronous DRAM is accessed.

Writes to the synchronous DRAM mode register use the address bus rather than the data bus. If the value to be set is X and the SDMR address is Y, the value X is written in the synchronous DRAM mode register by writing in address X + Y. Since, with a 32-bit bus width, A0 of the synchronous DRAM is connected to A2 of the chip and A1 of the synchronous DRAM is connected to A3 of the chip, the value actually written to the synchronous DRAM is the X value shifted two bits right. With a 16-bit bus width, the value written is the X value shifted one bit right. For example, with a 32-bit bus width, when H'0230 is written to the SDMR register of area 2, random data is written to the address H'FFFFD000 (address Y) + H'08C0 (value X), or H'FFFFD8C0. As a result, H'0230 is written to the SDMR register. The range for value X is H'0000 to H'0FFC. When H'0230 is written to the SDMR register of area 3, random data is written to the address H'FFFFE000 (address Y) + H'08C0 (value X), or H'FFFFE8C0. As a result, H'0230 is written to the SDMR register. The range for value X is H'0000 to H'0FFC.

### 8.4.8 Refresh Timer Control/Status Register (RTCSR)

The refresh timer control/status register (RTCSR) is a 16-bit read/write register that specifies the refresh cycle, whether to generate an interrupt, and that interrupt's cycle. It is initialized to H'0000 by a power-on reset, but is not initialized by a manual reset or standby mode and holds its values unchanged. Make the RTCOR setting before setting bits CKS2 to CKS0 in RTCSR.

**Note:** Writing to the RTCSR differs from that to general registers to ensure the RTCSR is not rewritten incorrectly. Use the word-transfer instruction to set the upper byte as B'10100101 and the lower byte as the write data. For the byte-transfer instruction, writing is disabled. Read data in 16 bits. 0 is read from undefined bits.

### 8.4.9 Refresh Timer Counter (RTCNT)

RTCNT is a 16-bit read/write register. RTCNT is an 8-bit counter that counts up with input clocks. The clock select bits (CKS2 to CKS0) of RTCSR select the input clock. When RTCNT matches RTCOR, the CMF bit of RTCSR is set and RTCNT is cleared. RTCNT is initialized to H'00 by a power-on reset; it continues incrementing after a manual reset; it is not initialized by standby mode and holds its values unchanged.

Note: Writing to the RTCNT differs from that to general registers to ensure the RTCNT is not rewritten incorrectly. Use the word-transfer instruction to set the upper byte as B'10100101 and the lower byte as the write data. For the byte-transfer instruction, writing is disabled. Read data in 16 bits. 0 is read from undefined bits.

| Bit     | Bit Name | Initial Value | R/W | Description                                  |
|---------|----------|---------------|-----|----------------------------------------------|
| 15 to 8 | —        | 0             | R   | Reserved<br>These bits are always read as 0. |
| 7 to 0  | —        | 0             | R/W | 8-bit. counter                               |

### 8.4.10 Refresh Time Constant Register (RTCOR)

The refresh time constant register (RTCOR) is a 16-bit read/write register. The values of RTCOR and RTCNT (bottom 8 bits) are constantly compared. When the values match, the CMF of RTCSR is set and RTCNT is cleared to 0. When the refresh bit (RFSH) of the individual memory control register (MCR) is set to 1 and the refresh mode is set to auto refresh, a memory refresh cycle occurs when the CMF bit is set. RTCOR is initialized to H'00 by a power-on reset. It is not initialized by a manual reset or standby mode, but holds its contents. Make the RTCOR setting before setting bits CKS2 to CKS0 in RTCSR.

Note: Writing to the RTCOR differs from that to general registers to ensure the RTCOR is not rewritten incorrectly. Use the word-transfer instruction to set the upper byte as B'10100101 and the lower byte as the write data. For the byte-transfer instruction, writing is disabled. Read data in 16 bits. 0 is read from undefined bits.

| Bit     | Bit Name | Initial Value | R/W | Description                                  |
|---------|----------|---------------|-----|----------------------------------------------|
| 15 to 8 | —        | 0             | R   | Reserved<br>These bits are always read as 0. |
| 7 to 0  | —        | 0             | R/W | Upper limit of the counter (8 bits)          |

### 8.4.11 Refresh Count Register (RFCR)

The refresh count register (RFCR) is a 16-bit read/write register. It is a 10-bit counter that increments every time RTCOR and RTCNT match. When RFCR exceeds the count limit value set in the LMTS of RTCSR, RTCSR's OVF bit is set and RFCR clears. RFCR is initialized to H'0000 when a power-on reset is performed. It is not initialized by a manual reset or standby mode, but holds its contents.

**Note:** Writing to the RFCR differs from that to general registers to ensure the RFCR is not rewritten incorrectly. Use the word-transfer instruction to set the MSB and followed six bits of upper bytes as B'101001 and remaining bits as the write data. For the byte-transfer instruction, writing is disabled. Read data in 16 bits. 0 is read from undefined bits.

| Bit      | Bit Name | Initial Value | R/W | Description                                  |
|----------|----------|---------------|-----|----------------------------------------------|
| 15 to 10 | —        | 0             | R   | Reserved<br>These bits are always read as 0. |
| 9 to 0   | —        | 0             | R/W | 10-bit counter                               |

## 8.5 Operation

### 8.5.1 Endian/Access Size and Data Alignment

This LSI supports both big endian, in which the 0 address is the most significant byte in the byte data, and little endian, in which the 0 address is the least significant byte. This switchover is designated by an external pin (MD5 pin) at the time of a power-on reset. After a power-on reset, big endian is engaged when MD5 is low; little endian is engaged when MD5 is high.

Three data bus widths are available for ordinary memory (byte, word, longword) and two data bus widths (word and longword) for synchronous DRAM. For the PCMCIA interface, choose from byte and word. This means data alignment is done by matching the device's data width and endian. The access unit must also be matched to the device's bus width. This also means that when longword data is read from a byte-width device, the read operation must happen 4 times. In this LSI, data alignment and conversion of data length is performed automatically between the respective interfaces.

Tables 8.11 through 8.16 show the relationship between endian, device data width, and access unit.

## 8.5.2 Description of Areas

**Area 0:** Area 0 physical addresses A28 to A26 are 000. Addresses A31 to A29 are ignored and the address range is  $H'00000000 + H'20000000 \times n - H'03FFFFFF + H'20000000 \times n$  ( $n = 0$  to 6 and  $n = 1$  to 6 are the shadow spaces).

Ordinary memories such as SRAM, ROM, and burst ROM can be connected to this space. Byte, word, or longword can be selected as the bus width using external pins MD3 and MD4. When the area 0 space is accessed, a  $\overline{CS0}$  signal is asserted. An  $\overline{RD}$  signal that can be used as  $\overline{OE}$  and the  $\overline{WE0}$  to  $\overline{WE3}$  signals for write control are also asserted. The number of bus cycles is selected between 0 and 10 wait cycles using the A0W2 to A0W0 bits of WCR2. When the burst function is used, the bus cycle pitch of the burst cycle is determined within a range of 2 to 10 according to the number of waits.

**Area 1:** Area 1 physical addresses A28 to A26 are 001. Addresses A31 to A29 are ignored and the address range is  $H'04000000 + H'20000000 \times n - H'07FFFFFF + H'20000000 \times n$  ( $n = 0$  to 6 and  $n = 1$  to 6 are the shadow spaces).

Area 1 is the area specifically for the internal peripheral modules. The external memories cannot be connected.

Control registers of peripheral modules shown below are mapped to this area 1. Their addresses are physical address, to which logical addresses can be mapped with the MMU enabled:

DMAC, PORT, SCIF, ADC, DAC, INTC (except INTEVT, IPRA, IPRB)

Those registers must be set not to be cached.

**Area 2:** Area 2 physical addresses A28 to A26 are 010. Addresses A31 to A29 are ignored and the address range is  $H'08000000 + H'20000000 \times n - H'0BFFFFFF + H'20000000 \times n$  ( $n = 0$  to 6 and  $n = 1$  to 6 are the shadow spaces).

Ordinary memories like SRAM and ROM, as well as synchronous DRAM, can be connected to this space. Byte, word, or longword can be selected as the bus width using the A2SZ1 to A2SZ0 bits of BCR2 for ordinary memory.

When the area 2 space is accessed, a  $\overline{CS2}$  signal is asserted. When ordinary memories are connected, an  $\overline{RD}$  signal that can be used as  $\overline{OE}$  and the  $\overline{WE0}$  to  $\overline{WE3}$  signals for write control are also asserted and the number of bus cycles is selected between 0 and 3 wait cycles using the A2W1 to A2W0 bits of WCR2.

When synchronous DRAM is connected, the  $\overline{RASU}$ ,  $\overline{RASL}$  signal,  $\overline{CASU}$ ,  $\overline{CASL}$  signal,  $RD/\overline{WR}$  signal, and byte controls  $\overline{DQMHH}$ ,  $\overline{DQMLH}$ ,  $\overline{DQMLH}$ , and  $\overline{DQMLL}$  are all asserted and addresses multiplexed. Control of  $\overline{RASU}$ ,  $\overline{RASL}$ ,  $\overline{CASU}$ ,  $\overline{CASL}$ , data timing, and address multiplexing is set with MCR.

**Area 3:** Area 3 physical addresses A28 to A26 are 011. Addresses A31 to A29 are ignored and the address range is  $H'0C000000 + H'20000000 \times n - H'0FFFFFFF + H'20000000 \times n$  ( $n = 0$  to 6 and  $n = 1$  to 6 are the shadow spaces).

Ordinary memories like SRAM and ROM, as well as synchronous DRAM, can be connected to this space. Byte, word or longword can be selected as the bus width using the A3SZ1 to A3SZ0 bits of BCR2 for ordinary memory.

When area 3 space is accessed,  $\overline{CS3}$  is asserted.

When ordinary memories are connected, an RD signal that can be used as  $\overline{OE}$  and the  $\overline{WE0}$  to  $\overline{WE3}$  signals for write control are asserted and the number of bus cycles is selected between 0 and 3 wait cycles using the A3W1 to A3W0 bits of WCR2.

When synchronous DRAM is connected, the  $\overline{RASU}$ ,  $\overline{RASL}$  signal,  $\overline{CASU}$ ,  $\overline{CASL}$  signal, RD/ $\overline{WR}$  signal, and byte controls  $\overline{DQMHHL}$ ,  $\overline{DQMHL}$ ,  $\overline{DQMLH}$ , and  $\overline{DQMLL}$  are all asserted and addresses multiplexed. Control of  $\overline{RAS}$ ,  $\overline{CAS}$ , and data timing and of address multiplexing is set with MCR.

**Area 4:** Area 4 physical addresses A28 to A26 are 100. Addresses A31 to A29 are ignored and the address range is  $H'10000000 + H'20000000 \times n - H'13FFFFFF + H'20000000 \times n$  ( $n = 0$  to 6 and  $n = 1$  to 6 are the shadow spaces).

Only ordinary memories like SRAM and ROM can be connected to this space. Byte, word, or longword can be selected as the bus width using the A4SZ1 to A4SZ0 bits of BCR2. When the area 4 space is accessed, a  $\overline{CS4}$  signal is asserted. An RD signal that can be used as  $\overline{OE}$  and the  $\overline{WE0}$  to  $\overline{WE3}$  signals for write control are also asserted. The number of bus cycles is selected between 0 and 10 wait cycles using the A4W2 to A4W0 bits of WCR2.

**Area 5:** Area 5 physical addresses A28 to A26 are 101. Addresses A31 to A29 are ignored and the address range is the 64 Mbytes at  $H'14000000 + H'20000000 \times n - H'17FFFFFF + H'20000000 \times n$  ( $n = 0$  to 6 and  $n = 1$  to 6 are the shadow spaces).

Ordinary memories like SRAM and ROM as well as burst ROM and PCMCIA interfaces can be connected to this space. When the PCMCIA interface is used, the IC memory card interface address range comprises the 32 Mbytes at  $H'14000000 + H'20000000 \times n$  to  $H'15FFFFFF + H'20000000 \times n$  (where  $n = 0$  to 6, and  $n = 1$  to 6 represents shadow space), and the I/O card interface address range comprises the 32 Mbytes at  $H'16000000 + H'20000000 \times n$  to  $H'17FFFFFF + H'20000000 \times n$  (where  $n = 0$  to 6, and  $n = 1$  to 6 represents shadow space).

For ordinary memory and burst ROM, byte, word, or longword can be selected as the bus width using the A5SZ1 to A5SZ0 bits of BCR2. For the PCMCIA interface, byte, and word can be selected as the bus width using the A5SZ1 to A5SZ0 bits of BCR2.

When the area 5 space is accessed and ordinary memory is connected, a  $\overline{CS5}$  signal is asserted. An  $\overline{RD}$  signal that can be used as  $\overline{OE}$  and the  $\overline{WE0}$  to  $\overline{WE3}$  signals for write control are also asserted. When the PCMCIA interface is used, the  $\overline{CE1A}$  signal,  $\overline{CE2A}$  signal,  $\overline{RD}$  signal as  $\overline{OE}$  signal, and  $\overline{WE1}$ ,  $\overline{ICIORD}$ , and  $\overline{ICIOWR}$  signals are asserted.

The number of bus cycles is selected between 0 and 10 wait cycles using the A5W2 to A5W0 bits of WCR2. With the PCMCIA interface, from 0 to 38 wait cycles can be selected using the A5W2 to A5W0 bits of WCR2 and the A5W3 bit of PCR. In addition, any number of waits can be inserted in each bus cycle by means of the external wait pin ( $\overline{WAIT}$ ). When a burst function is used, the bus cycle pitch of the burst cycle is determined within a range of 2 to 11 (2 to 39 for the PCMCIA interface) according to the number of waits. The setup and hold times of address/ $\overline{CS5}$  for the read/write strobe signals can be set in the range 0.5 to 7.5 using A5TED2 to A5TED0 and A5TEH2 to A5TEH0 bits of the PCR register.

**Area 6:** Area 6 physical addresses A28 to A26 are 110. Addresses A31 to A29 are ignored and the address range is the 64 Mbytes at  $H'18000000 + H'20000000 \times n - H'1BFFFFFF + H'20000000 \times n$  ( $n = 0$  to 6 and  $n = 1$  to 6 are the shadow spaces).

Ordinary memories like SRAM and ROM as well as burst ROM and PCMCIA interfaces can be connected to this space. When the PCMCIA interface is used, the IC memory card interface address range is 32 Mbytes at  $H'18000000 + H'20000000 \times n - H'19FFFFFF + H'20000000 \times n$  and the I/O card interface address range is 32 Mbytes at  $H'1A000000 + H'20000000 \times n - H'1BFFFFFF + H'20000000 \times n$  ( $n = 0$  to 6 and  $n = 1$  to 6 are the shadow spaces).

For ordinary memory and burst ROM, byte, word, or longword can be selected as the bus width using the A6SZ1 to A6SZ0 bits of BCR2. For the PCMCIA interface, byte, and word can be selected as the bus width using the A6SZ1 to A6SZ0 bits of BCR2.

When the area 6 space is accessed and ordinary memory is connected, a  $\overline{CS6}$  signal is asserted. An  $\overline{RD}$  signal that can be used as  $\overline{OE}$  and the  $\overline{WE0}$  to  $\overline{WE3}$  signals for write control are also asserted. When the PCMCIA interface is used, the  $\overline{CE1B}$  signal,  $\overline{CE2B}$  signal,  $\overline{RD}$  signal as  $\overline{OE}$  signal, and  $\overline{WE}$ ,  $\overline{ICIORD}$ , and  $\overline{ICIOWR}$  signals are asserted.

The number of bus cycles is selected between 0 and 10 wait cycles using the A6W2 to A6W0 bits of WCR2. With the PCMCIA interface, from 0 to 38 wait cycles can be selected using the A6W2 to A6W0 bits of WCR2 and the A6W3 bit of PCR. In addition, any number of waits can be inserted in each bus cycle by means of the external wait pin ( $\overline{WAIT}$ ). The bus cycle pitch of the burst cycle is determined within a range of 2 to 11 (2 to 39 for the PCMCIA interface) according to the number of waits. The setup and hold times of address/ $\overline{CS6}$  for the read/write strobe signals can be set in the range 0.5 to 7.5 using A6TED2 to A6TED0 and A6TEH2 to A6TEH0 bits of the PCR register.

### 8.5.3 Basic Interface

**Basic Timing:** The basic interface of this LSI uses strobe signal output in consideration of the fact that mainly static RAM will be directly connected. Figure 8.5 shows the basic timing of normal space accesses. A no-wait normal access is completed in two cycles. The  $\overline{BS}$  signal is asserted for one cycle to indicate the start of a bus cycle. The  $\overline{CSn}$  signal is negated on the T2 clock falling edge to secure the negation period. Therefore, in case of access at minimum pitch, there is a half-cycle negation period.

There is no access size specification when reading. The correct access start address is output in the least significant bit of the address, but since there is no access size specification, 32 bits are always read in case of a 32-bit device, and 16 bits in case of a 16-bit device. When writing, only the  $\overline{WE}$  signal for the byte to be written is asserted. For details, see section 8.5.1, Endian/Access Size and Data Alignment.

Read/write for cache fill or write-back follows the set bus width and transfers a total of 16 bytes continuously. The bus is not released during this transfer. For cache misses that occur during byte or word operand accesses or branching to odd word boundaries, the fill is always performed by longword accesses on the chip-external interface. Write-through-area write access and non-cacheable read/write access are based on the actual address size.

**Figure 8.5 Basic Timing of Basic Interface**

Figures 8.6, 8.7, and 8.8 show examples of connection to 32-, 16-, and 8-bit data-width static RAM, respectively.

**Figure 8.6 Example of 32-Bit Data-Width Static RAM Connection**

**Figure 8.7 Example of 16-Bit Data-Width Static RAM Connection**

**Figure 8.8 Example of 8-Bit Data-Width Static RAM Connection**

**Wait State Control:** Wait state insertion on the basic interface can be controlled by the WCR2 settings. If the WCR2 wait specification bits corresponding to a particular area are not zero, a software wait is inserted in accordance with that specification. For details, see section 8.4.4, Wait State Control Register 2 (WCR2)

The specified number of  $T_w$  cycles are inserted as wait cycles using the basic interface wait timing shown in figure 8.9.

**Figure 8.9 Basic Interface Wait Timing (Software Wait Only)**

When software wait insertion is specified by WCR2, the external wait input  $\overline{\text{WAIT}}$  signal is also sampled.  $\overline{\text{WAIT}}$  pin sampling is shown in figure 8.10. A 2-cycle wait is specified as a software wait. Sampling is performed at the transition from the  $T_w$  state to the  $T_2$  state; therefore, if the  $\overline{\text{WAIT}}$  signal has no effect if asserted in the  $T_1$  cycle or the first  $T_w$  cycle.

When the WAITSEL bit in the WCR1 register is set to 1, the  $\overline{\text{WAIT}}$  signal is sampled at the falling edge of the clock. If the setup time and hold times with respect to the falling edge of the clock are not satisfied, the value sampled at the next falling edge is used.

However, the  $\overline{\text{WAIT}}$  signal is ignored in the following cases:

- In 16-byte DMA transfer or dual addressing mode, or when writing data to the external address area
- In 16-byte DMA transfer or single addressing mode, or when transferring data from an external device with DACK to the external address area
- When accessing cache for write back

**Figure 8.10 Basic Interface Wait State Timing (Wait State Insertion by  $\overline{\text{WAIT}}$  Signal  
WAITSEL = 1)**

## 8.5.4 Synchronous DRAM Interface

- Synchronous DRAM Direct Connection

Since synchronous DRAM can be selected by the  $\overline{CS}$  signal, physical space areas 2 and 3 can be connected using  $\overline{RAS}$  and other control signals in common. If the memory type bits (DRAMTP2 to 0) in BCR1 are set to 010, area 2 is ordinary memory space and area 3 is synchronous DRAM space; if set to 011, areas 2 and 3 are both synchronous DRAM space. However, do not access to the synchronous DRAM when clock ratio is I $\phi$ :B $\phi$  = 1:1.

With this LSI, burst length 1 burst read/single write mode is supported as the synchronous DRAM operating mode. A data bus width of 16 or 32 bits can be selected. A 16-byte burst transfer is performed in a cache fill/write-back cycle, and only one access is performed in a write-through area write or a non-cacheable area read/write.

The control signals for direct connection of synchronous DRAM are  $\overline{RASL}$ ,  $\overline{RASU}$ ,  $\overline{CASL}$ ,  $\overline{CASU}$ ,  $RD/\overline{WR}$ ,  $\overline{CS2}$  or  $\overline{CS3}$ ,  $\overline{DQMUU}$ ,  $\overline{DQMUL}$ ,  $\overline{DQMLU}$ ,  $\overline{DQMLL}$ , and CKE. All the signals other than  $\overline{CS2}$  and  $\overline{CS3}$  are common to all areas, and signals other than CKE are valid and fetched to the synchronous DRAM only when  $\overline{CS2}$  or  $\overline{CS3}$  is asserted. Synchronous DRAM can therefore be connected in parallel to a number of areas. CKE is negated (low) only when self-refreshing is performed, and is always asserted (high) at other times.

In the refresh cycle and mode-register write cycle,  $\overline{RASU}$  and  $\overline{RASL}$  or  $\overline{CASU}$  and  $\overline{CASL}$  are output.

Commands for synchronous DRAM are specified by  $\overline{RASL}$ ,  $\overline{RASU}$ ,  $\overline{CASL}$ ,  $\overline{CASU}$ ,  $RD/\overline{WR}$ , and special address signals. The commands are NOP, auto-refresh (REF), self-refresh (SELF), precharge all banks (PALL), row address strobe bank active (ACTV), read (READ), read with precharge (READA), write (WRIT), write with precharge (WRITA), and mode register write (MRS).

Byte specification is performed by  $\overline{DQMUU}$ ,  $\overline{DQMUL}$ ,  $\overline{DQMLU}$ , and  $\overline{DQMLL}$ . A read/write is performed for the byte for which the corresponding DQM is low. In big-endian mode,  $\overline{DQMUU}$  specifies an access to address  $4n$ , and  $\overline{DQMLL}$  specifies an access to address  $4n + 3$ . In little-endian mode,  $\overline{DQMUU}$  specifies an access to address  $4n + 3$ , and  $\overline{DQMLL}$  specifies an access to address  $4n$ .

Figures 8.11 shows examples of the connection of two  $1M \times 16\text{-bit} \times 4\text{-bank}$  synchronous DRAMs and figure 8.12 shows one  $1M \times 16\text{-bit} \times 4\text{-bank}$  synchronous DRAM, respectively.

**Figure 8.11 Example of 64-Mbit Synchronous DRAM Connection (32-Bit Bus Width)**

**Figure 8.12 Example of 64-Mbit Synchronous DRAM (16-Bit Bus Width)**

- Address Multiplexing

Synchronous DRAM can be connected without external multiplexing circuitry in accordance with the address multiplex specification bits AMX3-AMX0 in MCR. Table 8.17 shows the relationship between the address multiplex specification bits and the bits output at the address pins.

A25 to A17 and A0 are not multiplexed; the original values are always output at these pins.

When A0, the LSB of the synchronous DRAM address, is connected to this LSI, it performs longword address specification. Connection should therefore be made in the following order: connect pin A0 of the synchronous DRAM to pin A2 of this LSI, then connect pin A1 to pin A3.

Table 8.18 shows an example of the connection of address pins when AMX[3:0] = 0100 with 32-bit bus width.

**Table 8.17 Relationship between Bus Width, AMX, and Address Multiplex Output**

| Bus Width | Memory Type                            | Setting |      |      |      | Output Timing  | External Address Pins |     |     |                   |                   |                   |                   |                   |                   |  |
|-----------|----------------------------------------|---------|------|------|------|----------------|-----------------------|-----|-----|-------------------|-------------------|-------------------|-------------------|-------------------|-------------------|--|
|           |                                        | AMX3    | AMX2 | AMX1 | AMX0 |                | A1 to A8              | A9  | A10 | A11               | A12               | A13               | A14               | A15               | A16               |  |
| 32 bits   | 4M × 16 bits × 4 banks <sup>*1</sup>   | 1       | 1    | 0    | 1    | Column address | A1 to A8              | A9  | A10 | A11               | L/H <sup>*3</sup> | A13               | A23               | A24 <sup>*4</sup> | A25 <sup>*4</sup> |  |
|           |                                        |         |      |      |      | Row address    | A10 to A17            | A18 | A19 | A20               | A21               | A22               | A23               | A24               | A25 <sup>*4</sup> |  |
|           | 2M × 16 bits × 4 banks <sup>*2</sup>   | 0       | 1    | 0    | 1    | Column address | A1 to A8              | A9  | A10 | A11               | L/H <sup>*3</sup> | A13               | A23 <sup>*4</sup> | A24 <sup>*4</sup> |                   |  |
|           |                                        |         |      |      |      | Row address    | A10 to A17            | A18 | A19 | A20               | A21               | A22               | A23 <sup>*4</sup> | A24 <sup>*4</sup> |                   |  |
|           | 1M × 16 bits × 4 banks <sup>*2</sup>   | 0       | 1    | 0    | 0    | Column address | A1 to A8              | A9  | A10 | A11               | L/H <sup>*3</sup> | A13               | A22 <sup>*4</sup> | A23 <sup>*4</sup> |                   |  |
|           |                                        |         |      |      |      | Row address    | A9 to A16             | A17 | A18 | A19               | A20               | A21               | A22 <sup>*4</sup> | A23 <sup>*4</sup> |                   |  |

- Burst Read

Figure 8.13 shows the timing chart for a burst read. In the example below, it is assumed that four 2M × 8-bit synchronous DRAMs are connected and a 32-bit data width is used, and the burst length is 1. Following the Tr cycle in which ACTV command output is performed, a READ command is issued in the Tc1, Tc2, and Tc3 cycles, and a READA command in the Tc4 cycle, and the read data is accepted on the rising edge of the external command clock (CKIO) from cycle Td1 to cycle Td4. The Tpc cycle is used to wait for completion of auto-precharge based on the READA command inside the synchronous DRAM; no new access command can be issued to the same bank during this cycle, but access to synchronous DRAM for another area is possible. In the this LSI, the number of Tpc cycles is determined by the TPC bit specification in MCR, and commands cannot be issued for the same synchronous DRAM during this interval.

The example in figure 8.13 shows the basic timing. To connect low-speed synchronous DRAM, the cycle can be extended by setting WCR2 and MCR bits. The number of cycles from the ACTV command output cycle,  $T_r$ , to the READ command output cycle,  $T_{c1}$ , can be specified by the RCD bit in MCR, with a values of 0 to 3 specifying 1 to 4 cycles, respectively. In case of 2 or more cycles, a  $T_{rw}$  cycle, in which an NOP command is issued for the synchronous DRAM, is inserted between the  $T_r$  cycle and the  $T_c$  cycle. The number of cycles from READ and READA command output cycles  $T_{c1}$ - $T_{c4}$  to the first read data latch cycle,  $T_{d1}$ , can be specified as 1 to 3 cycles independently for areas 2 and 3 by means of A2W1 and A2W0 or A3W1 and A3W0 in WCR2. This number of cycles corresponds to the number of synchronous DRAM CAS latency cycles.

**Figure 8.13 Basic Timing for Synchronous DRAM Burst Read**

Figure 8.14 shows the burst read timing when RCD is set to 1, A3W1 and A3W0 are set to 10, and TPC is set to 1.

The  $\overline{BS}$  cycle, which is asserted for one cycle at the start of a bus cycle for normal space access, is asserted in each of cycles Td1 to Td4 in a synchronous DRAM cycle. When a burst read is performed, the address is updated each time  $\overline{CAS}$  is asserted. As the unit of burst transfer is 16 bytes, address updating is performed for A3 and A2 only (A3, A2, and A1 for a 16-bit bus width). The order of access is as follows: in a fill operation in the event of a cache miss, the missed data is read first, then 16-byte boundary data including the missed data is read in wraparound mode.

**Figure 8.14 Synchronous DRAM Burst Read Wait Specification Timing**

- Single Read

Figure 8.15 shows the timing when a single address read is performed. As the burst length is set to 1 in synchronous DRAM burst read/single write mode, only the required data is output. Consequently, no unnecessary bus cycles are generated even when a cache-through area is accessed.

Notes: 1. Command bit  
2. Column address

**Figure 8.15 Basic Timing for Synchronous DRAM Single Read**

- Burst Write

The timing chart for a burst write is shown in figure 8.16. In this LSI, a burst write occurs only in the event of cache write-back or 16-byte transfer by DMAC. In a burst write operation, following the  $T_r$  cycle in which ACTV command output is performed, a WRIT command is issued in the  $T_{c1}$ ,  $T_{c2}$ , and  $T_{c3}$  cycles, and a WRITA command that performs auto-precharge is issued in the  $T_{c4}$  cycle. In the write cycle, the write data is output at the same time as the write command. In case of the write with auto-precharge command, precharging of the relevant bank is performed in the synchronous DRAM after completion of the write command, and therefore no command can be issued for the same bank until precharging is completed. Consequently, in addition to the precharge wait cycle,  $T_{pc}$ , used in a read access, cycle  $Trw1$  is also added as a wait interval until precharging is started following the write command. Issuance of a new command for the same bank is postponed during this interval. The number of  $Trw1$  cycles can be specified by the  $TRWL$  bit in MCR.

Notes: 1. Command bit  
2. Column address

**Figure 8.16 Basic Timing for Synchronous DRAM Burst Write**

- Single Write

The basic timing chart for write access is shown in figure 8.17. In a single write operation, following the  $T_r$  cycle in which ACTV command output is performed, a WRITA command that performs auto-precharge is issued in the  $T_{c1}$  cycle. In the write cycle, the write data is output at the same time as the write command. In case of the write with auto-precharge command, precharging of the relevant bank is performed in the synchronous DRAM after completion of the write command, and therefore no command can be issued for the same bank until precharging is completed. Consequently, in addition to the precharge wait cycle,  $T_{pc}$ , used in a read access, cycle  $Trwl$  is also added as a wait interval until precharging is started following the write command. Issuance of a new command for the same bank is postponed during this interval. The number of  $Trwl$  cycles can be specified by the TRWL bit in MCR.

**Figure 8.17 Basic Timing for Synchronous DRAM Single Write**

- Bank Active

The synchronous DRAM bank function is used to support high-speed accesses to the same row address. When the RASD bit in MCR is 1, read/write command accesses are performed using commands without auto-precharge (READ, WRIT). In this case, precharging is not performed when the access ends. When accessing the same row address in the same bank, it is possible to issue the READ or WRIT command immediately, without issuing an ACTV command. As synchronous DRAM is internally divided into two or four banks, it is possible to activate one row address in each bank. If the next access is to a different row address, a PRE command is first issued to precharge the relevant bank, then when precharging is completed, the access is performed by issuing an ACTV command followed by a READ or WRIT command. If this is followed by an access to a different row address, the access time will be longer because of the precharging performed after the access request is issued.

In a write, when auto-precharge is performed, a command cannot be issued for a period of  $Trw1 + Tpc$  cycles after issuance of the WRITA command. When bank active mode is used, READ or WRIT commands can be issued successively if the row address is the same. The number of cycles can thus be reduced by  $Trw1 + Tpc$  cycles for each write. The number of cycles between issuance of the precharge command and the row address strobe command is determined by the TPC bit in MCR.

Whether faster execution speed is achieved by use of bank active mode or by use of basic access is determined by the probability of accessing the same row address ( $P1$ ), and the average number of cycles from completion of one access to the next access ( $Ta$ ). If  $Ta$  is greater than  $Tpc$ , the delay due to the precharge wait when reading is imperceptible. If  $Ta$  is greater than  $Trw1 + Tpc$ , the delay due to the precharge wait when writing is imperceptible. In this case, the access speed for bank active mode and basic access is determined by the number of cycles from the start of access to issuance of the read/write command:  $(Tpc + Tred) \times (1 - P1)$  and  $Tred$ , respectively.

There is a limit on  $Tras$ , the time for placing each bank in the active state. If there is no guarantee that there will not be a cache hit and another row address will be accessed within the period in which this value is maintained by program execution, it is necessary to set auto-refresh and set the refresh cycle to no more than the maximum value of  $Tras$ . In this way, it is possible to observe the restrictions on the maximum active state time for each bank. If auto-refresh is not used, measures must be taken in the program to ensure that the banks do not remain active for longer than the prescribed time.

A burst read cycle without auto-precharge is shown in figure 8.18, a burst read cycle for the same row address in figure 8.19, and a burst read cycle for different row addresses in figure 8.20. Similarly, a burst write cycle without auto-precharge is shown in figure 8.21, a burst write cycle for the same row address in figure 8.22, and a burst write cycle for different row addresses in figure 8.23.

A Tnop cycle, in which no operation is performed, is inserted before the Tc1 cycle in which the READ command is issued in figure 8.19, but when synchronous DRAM is read, there is a two-cycle latency for the  $\overline{\text{DQMxx}}$  signal that performs the byte specification. If the Tc1 cycle were performed immediately, without inserting a Tnop cycle, it would not be possible to perform the  $\overline{\text{DQMxx}}$  signal specification for Td1 cycle data output. This is the reason for inserting the Tnop cycle. If the CAS latency is two cycles or longer, Tnop cycle insertion is not performed, since the timing requirements will be met even if the  $\overline{\text{DQMxx}}$  signal is set after the Tc1 cycle.

When bank active mode is set, if only accesses to the respective banks in the area 3 space are considered, as long as accesses to the same row address continue, the operation starts with the cycle in figure 8.18 or 8.21, followed by repetition of the cycle in figure 8.19 or 8.22. An access to a different area 3 space during this time has no effect. If there is an access to a different row address in the bank active state, after this is detected the bus cycle in figure 8.19 or 8.22 is executed instead of that in figure 8.19 or 8.22. In bank active mode, too, all banks become inactive after a refresh cycle or after the bus is released as the result of bus arbitration.

- Refreshing

The bus state controller is provided with a function for controlling synchronous DRAM refreshing. Auto-refreshing can be performed by clearing the RMODE bit to 0 and setting the RFSH bit to 1 in MCR. If synchronous DRAM is not accessed for a long period, self-refresh mode, in which the power consumption for data retention is low, can be activated by setting both the RMODE bit and the RFSH bit to 1.

## 1. Auto-Refreshing

Figure 8.24 shows the auto-refreshing operation.

Refreshing is performed at intervals determined by the input clock selected by bits CKS2-0 in RTCSR, and the value set in RTCOR. The value of bits CKS2-0 in RTCOR should be set so as to satisfy the refresh interval stipulation for the synchronous DRAM used. First make the settings for RTCOR, RTCNT, and the RMODE and RFSH bits in MCR, then make the CKS2-CKS0 setting. When the clock is selected by CKS2-CKS0, RTCNT starts counting up from the value at that time. The RTCNT value is constantly compared with the RTCOR value, and if the two values are the same, a refresh request is generated and an auto-refresh is performed. At the same time, RTCNT is cleared to zero and the count-up is restarted. Figure 8.25 shows the auto-refresh cycle timing.

All-bank precharging is performed in the  $T_p$  cycle, then an REF command is issued in the  $TR_r$  cycle following the interval specified by the TPC bits in MCR. After the  $TR_r$  cycle, new command output cannot be performed for the duration of the number of cycles specified by the TRAS bits in MCR plus the number of cycles specified by the TPC bits in MCR. The TRAS and TPC bits must be set so as to satisfy the synchronous DRAM refresh cycle time stipulation (active/active command delay time).

Auto-refreshing is performed in normal operation, in sleep mode, and in case of a manual reset.

**Figure 8.24 Auto-Refresh Operation**

**Figure 8.25 Synchronous DRAM Auto-Refresh Timing**

## 2. Self-Refreshing

Self-refresh mode is a kind of standby mode in which the refresh timing and refresh addresses are generated within the synchronous DRAM. Self-refreshing is activated by setting both the RMODE bit and the RFSH bit to 1. The self-refresh state is maintained while the CKE signal is low. Synchronous DRAM cannot be accessed while in the self-refresh state. Self-refresh mode is cleared by clearing the RMODE bit to 0. After self-refresh mode has been cleared, command issuance is disabled for the number of cycles specified by the TPC bits in MCR. Self-refresh timing is shown in figure 8.26. Settings must be made so that self-refresh clearing and data retention are performed correctly, and auto-refreshing is performed at the correct intervals. When self-refreshing is activated from the state in which auto-refreshing is set, or when exiting standby mode other than through a power-on reset, auto-refreshing is restarted if RFSH is set to 1 and RMODE is cleared to 0 when self-refresh mode is cleared. If the transition from clearing of self-refresh mode to the start of auto-refreshing takes time, this time should be taken into consideration when setting the initial value of RTCNT. Making the RTCNT value 1 less than the RTCOR value will enable refreshing to be started immediately. After self-refreshing has been set, the self-refresh state continues even if the chip standby state is entered using the this LSI standby function, and is maintained even after recovery from standby mode other than through a power-on reset. In case of a power-on reset, the bus state controller's registers are initialized, and therefore the self-refresh state is cleared. Self-refreshing is performed in normal operation, in sleep mode, in standby mode, and in case of a manual reset.

When using synchronous DRAM, use the following procedure to initiate self-refreshing.

1. Clear the refresh control bit to 0.
2. Write H'00 to the RTCNT register.
3. Set the refresh control bit and refresh mode bit to 1.

**Figure 8.26 Synchronous DRAM Self-Refresh Timing**

### 3. Relationship between Refresh Requests and Bus Cycle Requests

If a refresh request is generated during execution of a bus cycle, execution of the refresh is deferred until the bus cycle is completed. If a refresh request occurs when the bus has been released by the bus arbiter, refresh execution is deferred until the bus is acquired. If a match between RTCNT and RTCOR occurs while a refresh is waiting to be executed, so that a new refresh request is generated, the previous refresh request is eliminated. In order for refreshing to be performed normally, care must be taken to ensure that no bus cycle or bus mastership occurs that is longer than the refresh interval. When a refresh request is generated, the  $\overline{\text{IRQOUT}}$  pin is asserted (driven low). Therefore, normal refreshing can be performed by having the  $\overline{\text{IRQOUT}}$  pin monitored by a bus master other than this LSI requesting the bus, or the bus arbiter, and returning the bus to this LSI. When refreshing is started, and if no other interrupt request has been generated, the  $\overline{\text{IRQOUT}}$  pin is negated (driven high).

- Power-On Sequence

In order to use synchronous DRAM, mode setting must first be performed after powering on. To perform synchronous DRAM initialization correctly, the bus state controller registers must first be set, followed by a write to the synchronous DRAM mode register. In synchronous DRAM mode register setting, the address signal value at that time is latched by a combination of the  $\overline{\text{RAS}}$ ,  $\overline{\text{CAS}}$ , and  $\text{RD}/\overline{\text{WR}}$  signals. If the value to be set is X, the bus state controller provides for value X to be written to the synchronous DRAM mode register by performing a write to address  $\text{H'FFFFD000} + \text{X}$  for area 2 synchronous DRAM, and to address  $\text{H'FFFFE000} + \text{X}$  for area 3 synchronous DRAM. In this operation the data is ignored, but the mode write is performed as a byte-size access. To set burst read/single write, CAS latency 1 to 3, wrap type = sequential, and burst length 1 supported by this LSI, arbitrary data is written in a byte-size access to the following addresses.

|           |               | Area 2   | Area 3   |
|-----------|---------------|----------|----------|
| 32-bit    | CAS latency 1 | FFFFD840 | FFFFE840 |
| Bus width | CAS latency 2 | FFFFD880 | FFFFE880 |
|           | CAS latency 3 | FFFFD8C0 | FFFFE8C0 |
|           |               |          |          |
|           |               | Area 2   | Area 3   |
| 16-bit    | CAS latency 1 | FFFFD420 | FFFFE420 |
| Bus width | CAS latency 2 | FFFFD440 | FFFFE440 |
|           | CAS latency 3 | FFFFD460 | FFFFE460 |

Mode register setting timing is shown in figure 8.27.

As a result of the write to address  $\text{H'FFFFD000} + \text{X}$  or  $\text{H'FFFFE000} + \text{X}$ , a precharge all banks (PALL) command is first issued in the  $\text{TRp1}$  cycle, then a mode register write command is issued in the  $\text{TMw1}$  cycle.

Address signals, when the mode-register write command is issued, are as follows:

|           |        |                                       |
|-----------|--------|---------------------------------------|
| 32-bit    | A15-A9 | 0000100 (burst read and single write) |
| Bus width | A8-A6  | CAS latency                           |
|           | A5     | 0 (burst type = sequential)           |
|           | A4-A2  | 000 (burst length 1)                  |
|           |        |                                       |
| 16-bit    | A14-A8 | 0000100 (burst read and single write) |
| Bus width | A7-A5  | CAS latency                           |
|           | A4     | 0 (burst type = sequential)           |
|           | A3-A1  | 000 (burst length 1)                  |

Before mode register setting, a 100  $\mu$ s idle time (depending on the memory manufacturer) must be guaranteed after powering on requested by the synchronous DRAM. If the reset signal pulse width is greater than this idle time, there is no problem in performing mode register setting immediately. The number of dummy auto-refresh cycles specified by the manufacturer (usually 8) or more must be executed. This is usually achieved automatically while various kinds of initialization are being performed after auto-refresh setting, but a way of carrying this out more dependably is to set a short refresh request generation interval just while these dummy cycles are being executed. With simple read or write access, the address counter in the synchronous DRAM used for auto-refreshing is not initialized, and so the cycle must always be an auto-refresh cycle.

**Figure 8.27 Synchronous DRAM Mode Write Timing**

### 8.5.5 Burst ROM Interface

Setting bits A0BST (1 to 0), A5BST (1 to 0), and A6BST (1 to 0) in BCR1 to a non-zero value allows burst ROM to be connected to areas 0, 5, and 6. The burst ROM interface provides high-speed access to ROM that has a nibble access function. The timing for nibble access to burst ROM is shown in figure 8.28. Two wait cycles are set. Basically, access is performed in the same way as for normal space, but when the first cycle ends the  $\overline{CS0}$  signal is not negated, and only the address is changed before the next access is executed. When 8-bit ROM is connected, the number of consecutive accesses can be set as 4, 8, or 16 by bits A0BST (1 to 0), A5BST (1 to 0), or A6BST (1 to 0). When 16-bit ROM is connected, 4 or 8 can be set in the same way. When 32-bit ROM is connected, only 4 can be set.

$\overline{WAIT}$  pin sampling is performed in the first access if one or more wait states are set, and is always performed in the second and subsequent accesses.

The second and subsequent access cycles also comprise two cycles when a burst ROM setting is made and the wait specification is 0. The timing in this case is shown in figure 8.29.

However, the  $\overline{WAIT}$  signal is ignored in the following cases:

- In 16-byte DMA transfer or dual addressing mode, or when writing data to the external address area
- In 16-byte DMA transfer or single addressing mode, or when transferring data from an external device with DACK to the external bus area
- When accessing cache for write back

**Figure 8.28 Burst ROM Wait Access Timing**

Note: For a write cycle, a basic bus cycle (write cycle) is performed.

**Figure 8.29 Burst ROM Basic Access Timing**

### 8.5.6 PCMCIA Interface

In this LSI, setting the A5PCM bit in BCR1 to 1 makes the bus interface for physical space area 5 an IC memory card and I/O card interface as stipulated in JEIDA version 4.2 (PCMCIA2.1).

Setting the A6PCM bit to 1 makes the bus interface for physical space area 6 an IC memory card and I/O card interface as stipulated in JEIDA version 4.2.

Figure 8.30 shows the PCMCIA space allocation.

When the PCMCIA interface is used, a bus size of 8 or 16 bits can be set by bits A5SZ1 and A5SZ0, or A6SZ1 and A6SZ0, in BCR2.

Figure 8.31 shows an example of PCMCIA card connection to this LSI. To enable active insertion of the PCMCIA cards (i.e. insertion or removal while system power is being supplied), a 3-state buffer must be connected between this LSI bus interface and the PCMCIA cards.

As operation in big-endian mode is not explicitly stipulated in the JEIDA/PCMCIA specifications, the PCMCIA interface for this LSI in big-endian mode is stipulated independently.

However, the  $\overline{\text{WAIT}}$  signal is ignored in the following cases:

- In 16-byte DMA transfer or dual addressing mode, or when writing data to the external address area
- In 16-byte DMA transfer or single addressing mode, or when transferring data from an external device with DACK to the external bus area
- When accessing cache for write back

**Figure 8.30 PCMCIA Space Allocation**

Figure 8.31 Example of PCMCIA Interface

**Memory Card Interface Basic Timing:** Figure 8.32 shows the basic timing for the PCMCIA IC memory card interface. When physical space areas 5 and 6 are designated as PCMCIA interface areas, bus accesses are automatically performed as IC memory card interface accesses.

With a high external bus frequency (CKIO), the setup and hold times for the address (A24 to A0), card enable ( $\overline{\text{CS5}}$ ,  $\overline{\text{CE2A}}$ ,  $\overline{\text{CS6}}$ ,  $\overline{\text{CE2B}}$ ), and write data (D15 to D0) in a write cycle, become insufficient with respect to  $\overline{\text{RD}}$  and  $\overline{\text{WR}}$  (the  $\overline{\text{WE}}$  pin in this LSI). This LSI provides for this by enabling setup and hold times to be set for physical space areas 5 and 6 in the PCR register. Also, software waits by means of a WCR2 register setting and hardware waits by means of the  $\overline{\text{WAIT}}$  pin can be inserted in the same way as for the basic interface. Figure 8.33 shows the PCMCIA memory bus wait timing.

**Figure 8.32 Basic Timing for PCMCIA Memory Card Interface**

**Figure 8.33 Wait Timing for PCMCIA Memory Card Interface**

**Memory Card Interface Burst Timing:** In this LSI, when the IC memory card interface is selected, page mode burst access mode can be used, for read access only, by setting bits A5BST1 and A5BST0 in BCR1 for physical space area 5, or bits A6BST1 and A6BST0 in BCR1 for area 6. This burst access mode is not stipulated in JEIDA version 4.2 (PCMCIA2.1), but allows high-speed data access using ROM provided with a burst mode, etc.

Burst access mode timing is shown in figures 8.34 and 8.35.

**Figure 8.34 Basic Timing for PCMCIA Memory Card Interface Burst Access**

**Figure 8.35 Wait Timing for PCMCIA Memory Card Interface Burst Access**

When the entire 32-Mbyte memory space is used as IC memory card interface space, the common memory/attribute memory switching signal  $\overline{REG}$  is generated using a port, etc. If 16-Mbytes or less of memory space is sufficient, using 16 Mbytes of memory space as common memory space and 16 Mbytes as attribute memory space enables the A24 pin to be used for the  $\overline{REG}$  signal.

**I/O Card Interface Timing:** Figures 8.36 and 8.37 show the timing for the PCMCIA I/O card interface.

Switching between the I/O card interface and the IC memory card interface is performed according to the accessed address. When PCMCIA is designed for physical space area 5, the bus access is automatically performed as an I/O card interface access when a physical address from H'16000000 to H'17FFFFFF is accessed. When PCMCIA is designated for physical space area 6, the bus access is automatically performed as an I/O card interface access when a physical address from H'1A000000 to H'1BFFFFFF is accessed.

When accessing a PCMCIA I/O card, the access should be performed using a non-cacheable area in virtual space (P2 or P3 space) or an area specified as non-cacheable by the MMU.

When an I/O card interface access is made to a PCMCIA card in little-endian mode, dynamic sizing of the I/O bus width is possible using the  $\overline{\text{IOIS16}}$  pin. When a 16-bit bus width is set for area 5 or 6, if the  $\overline{\text{IOIS16}}$  signal is high during a word-size I/O bus cycle, the I/O port is recognized as being 8 bits in width. In this case, a data access for only 8 bits is performed in the I/O bus cycle being executed, followed automatically by a data access for the remaining 8 bits.

Figure 8.38 shows the basic timing for dynamic bus sizing.

In big-endian mode, the  $\overline{\text{IOIS16}}$  signal is not supported.

In big-endian mode, the  $\overline{\text{IOIS16}}$  signal should be fixed low.

**Figure 8.36 Basic Timing for PCMCIA I/O Card Interface**

**Figure 8.37 Wait Timing for PCMCIA I/O Card Interface**

**Figure 8.38 Dynamic Bus Sizing Timing for PCMCIA I/O Card Interface**

### 8.5.7 Waits between Access Cycles

A problem associated with higher external memory bus operating frequencies is that data buffer turn-off on completion of a read from a low-speed device may be too slow, causing a collision with data in the next access. This results in lower reliability or incorrect operation. To avoid this problem, a data collision prevention feature has been provided. This memorizes the preceding access area and the kind of read/write. If there is a possibility of a bus collision when the next access is started, a wait cycle is inserted before the access cycle thus preventing a data collision. There are two cases in which a wait cycle is inserted: when an access is followed by an access to a different area, and when a read access is followed by a write access from this LSI. When this LSI performs consecutive write cycles, the data transfer direction is fixed (from this LSI to other memory) and there is no problem. With read accesses to the same area, in principle, data is output from the same data buffer, and wait cycle insertion is not performed. Bits AnIW1 and AnIW0 ( $n = 0, 2$  to 6) in WCR1 specify the number of idle cycles to be inserted between access cycles when a physical space area access is followed by an access to another area, or when this LSI performs a write access after a read access to physical space area  $n$ . If there is originally space between accesses, the number of idle cycles inserted is the specified number of idle cycles minus the number of empty cycles.

Waits are not inserted between accesses when bus arbitration is performed, since empty cycles are inserted for arbitration purposes.

Figure 8.39 Waits between Access Cycles

## 8.5.8 Bus Arbitration

When a bus release request ( $\overline{\text{BREQ}}$ ) is received from an external device, buses are released after the bus cycle being executed is completed and a bus grant signal ( $\overline{\text{BACK}}$ ) is output. The bus is not released during burst transfers for cache fills or a write back and TAS instruction execution between the read cycle and write cycle. Bus arbitration is not executed in multiple bus cycles that are generated when the data bus width is shorter than the access size; i.e. in the bus cycles when longword access is executed for the 8-bit memory. At the negation of  $\overline{\text{BREQ}}$ ,  $\overline{\text{BACK}}$  is negated and bus use is restarted. See Appendix B, Pin Functions, for the pin state when the bus is released.

This LSI sometimes needs to retrieve a bus it has released. For example, when memory generates a refresh request or an interrupt request internally, this LSI must perform the appropriate processing. This LSI has a bus request signal ( $\overline{\text{IRQOUT}}$ ) for this purpose. When it must retrieve the bus, it asserts the  $\overline{\text{IRQOUT}}$  signal. Devices asserting an external bus release request receive the assertion of the  $\overline{\text{IRQOUT}}$  signal and negate the  $\overline{\text{BREQ}}$  signal to release the bus. This LSI retrieves the bus and carries out the processing.

### $\overline{\text{IRQOUT}}$ Pin Assertion Conditions:

- When a memory refresh request has been generated but the refresh cycle has not yet begun
- When an interrupt is generated with an interrupt request level higher than the setting of the interrupt mask bits (I3 to I0) in the status register (SR). (This does not depend on the SR.BL bit.)

## 8.5.9 Bus Pull-Up

With this LSI, address pin pull-up can be performed when the bus is released by setting the PULA bit in BCR1 to 1. The address pins are pulled up for a 4-clock period after  $\overline{\text{BACK}}$  is asserted. Figure 8.40 shows the address pin pull-up timing. Similarly, data pin pull-up can be performed by setting the PULD bit in BCR1 to 1. The data pins should be pulled up when the data bus is not in use. The data pin pull-up timing for a read cycle is shown in figure 8.41, and the timing for a write cycle in figure 8.42.

Figure 8.40 Pins A25 to A0 Pull-Up Timing

**Figure 8.41 Pins D31 to D0 Pull-Up Timing (Read Cycle)**

**Figure 8.42 Pins D31 to D0 Pull-Up Timing (Write Cycle)**

## Section 9 Direct Memory Access Controller (DMAC)

This chip includes a four-channel direct memory access controller (DMAC). The DMAC can be used in place of the CPU to perform high-speed transfers between external devices that have DACK (transfer request acknowledge signal), external memory, memory-mapped external devices, and on-chip peripheral modules (SCIF, A/D converter, and D/A converter). Using the DMAC reduces the burden on the CPU and increases overall operating efficiency.

Figure 9.1 shows a block diagram of the DMAC.

### 9.1 Feature

The DMAC has the following features.

- Four channels
- Address space: Architecturally 4-Gbytes
- 8-bit, 16-bit, 32-bit, or 16-byte transfer (In 16-byte transfer, four 32-bit reads are executed, followed by four 32-bit writes.)
- Maximum transfer counter: 16 Mbytes (16777216 transfers)
- Supports dual address mode
  - Direct address transfer mode: The values specified in the DMAC registers indicates the transfer source and transfer destination. Two bus cycles are required for one data transfer.
  - Indirect address transfer mode: Data is transferred with the address stored prior to the address specified in the transfer source address in the DMAC. Other operations are the same as those of direct address transfer mode. This function is only valid in channel 3. Four bus cycles are required for one data transfer.
- Supports single address mode:
  - Either the transfer source or transfer destination peripheral device is accessed (selected) by means of the DACK signal, and the other device is accessed by address. One bus cycle is required for one data transfer.
- Channel functions: Transfer mode that can be specified is different in each channel.
  - Channel 0: External request can be accepted.
  - Channel 1: External request can be accepted.
  - Channel 2: This channel has a source address reload function, which reloads a source address for each 4 transfers.
  - Channel 3: In this channel, direct address transfer mode or indirect address transfer mode can be specified.
- Reload function: The value that was specified in the source address register can be automatically reloaded every 4 DMA transfers. This function is only valid in channel 2.

- Three type of Transfer requests
  - External request: From two  $\overline{\text{DREQ}}$  pins (channels 0 and 1 only).  $\overline{\text{DREQ}}$  can be detected either by the falling edge or by the low level.
  - On-chip module request: Requests from on-chip peripheral modules such as serial communications interface (SCIF), A/D converter (A/D), and a timer (CMT). This request can be accepted in all the channels.
  - Auto request: The transfer request is generated automatically within the DMAC.
- Selectable bus modes: Cycle-steal mode or burst mode
- Selectable channel priority levels:
 

Fixed mode: The channel priority is fixed.

Round-robin mode: The priority of the channel in which the execution request was accepted is made the lowest.
- Interrupt request: An interrupt request can be generated to the CPU after transfers end by the specified counts.

**Figure 9.1 DMAC Block Diagram**

## 9.2 Input/Output Pin

Table 9.1 shows the DMAC pins.

**Table 9.1 Pin Configuration**

| Channel | Name                    | Symbol                    | I/O | Function                                                                                   |
|---------|-------------------------|---------------------------|-----|--------------------------------------------------------------------------------------------|
| 0       | DMA transfer request    | $\overline{\text{DREQ0}}$ | I   | DMA transfer request input from external device to channel 0                               |
|         | DREQ acknowledge        | DACK0                     | O   | Strobe output to an external I/O at DMA transfer request from external device to channel 0 |
|         | DMA request acknowledge | DRAK0                     | O   | Output showing that $\overline{\text{DREQ0}}$ has been accepted                            |
| 1       | DMA transfer request    | $\overline{\text{DREQ1}}$ | I   | DMA transfer request input from external device to channel 1                               |
|         | DREQ acknowledge        | DACK1                     | O   | Strobe output to an external I/O at DMA transfer request from external device to channel 1 |
|         | DMA request acknowledge | DRAK1                     | O   | Output showing that $\overline{\text{DREQ1}}$ has been accepted                            |

## 9.3 Register Description

DMAC has a total of 17 registers. Each channel has four control registers. One other control register is shared by all channels.

Refer to section 23, List of Registers, for more details of the addresses and access sizes.

### Channel 0

- DMA source address register 0 (SAR0)
- DMA destination address register 0 (DAR0)
- DMA transfer count register 0 (DMATCR0)
- DMA channel control register 0 (CHCR0)

### Channel 1

- DMA source address register 1 (SAR1)
- DMA destination address register 1 (DAR1)
- DMA transfer count register 1 (DMATCR1)
- DMA channel control register 1 (CHCR1)

#### Channel 2

- DMA source address register 2 (SAR2)
- DMA destination address register 2 (DAR2)
- DMA transfer count register 2 (DMATCR2)
- DMA channel control register 2 (CHCR2)

#### Channel 3

- DMA source address register 3 (SAR3)
- DMA destination address register 3 (DAR3)
- DMA transfer count register 3 (DMATCR3)
- DMA channel control register 3 (CHCR3)
- DMA operation register (DMAOR)

### 9.3.1 DMA Source Address Registers 0 to 3 (SAR\_0 to SAR\_3)

DMA source address registers 0 to 3 (SAR\_0 to SAR\_3) are 32-bit read/write registers that specify the source address of a DMA transfer. These registers include count functions, and during a DMA transfer, these registers indicate the next source address.

To transfer data in 16 bits or in 32 bits, specify the address with 16-bit or 32-bit address boundary. When transferring data in 16-byte units, a 16-byte boundary (address 16n) must be set for the source address value. Specifying other addresses does not guarantee operation.

The initial value is undefined by resets. The previous value is held in standby mode.

When accessed in 16 bits, the other 16-bit data which has not been accessed is held.

### 9.3.2 DMA Destination Address Registers 0 to 3 (DAR\_0 to DAR\_3)

DMA destination address registers 0 to 3 (DAR\_0 to DAR\_3) are 32-bit read/write registers that specify the destination address of a DMA transfer. These registers include count functions, and during a DMA transfer, these registers indicate the next destination address.

To transfer data in 16 bits or in 32 bits, specify the address with 16-bit or 32-bit address boundary. Specifying other addresses does not guarantee operation.

The initial value is undefined by resets. The previous value is held in standby mode.

When accessed in 16 bits, the other 16-bit data which has not been accessed is held.

### 9.3.3 DMA Transfer Count Registers 0 to 3 (DMATCR\_0 to DMATCR\_3)

DMA transfer count registers 0 to 3 (DMATCR\_0 to DMATCR\_3) are 24-bit read/write registers that specify the DMA transfer count (bytes, words, or longwords) in each channel. The number of transfers is 1 when the setting is H'000001, and 16777216 (the maximum) when H'000000 is set. During a DMA transfer, these registers indicate the remaining transfer count.

To transfer data in 16 bytes, one 16-byte transfer (128 bits) counts one.

Upper eight bits in DMATCR are reserved. These bits are always read as 0. The write value should always be 0.

When using 16-byte transfer, an integral multiple of 4 (4n) must be set for the number of transfers to ensure normal operation.

The initial value is undefined by resets. The previous value is held in standby mode.

| Bit      | Bit Name | Initial Value | R/W | Description                                                                      |
|----------|----------|---------------|-----|----------------------------------------------------------------------------------|
| 31 to 24 | —        | —             | R   | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 23 to 0  | —        | —             | R/W | 24- bit register                                                                 |

### 9.3.4 DMA Channel Control Registers 0 to 3 (CHCR\_0 to CHCR\_3)

DMA channel control registers 0 to 3 (CHCR\_0 to CHCR\_3) are 32-bit read/write registers that specifies operation mode, transfer method, or others in each channel.

These register values are initialized to 0s by resets. The previous value is held in standby mode.

When accessed in 16 bits, the other 16-bit data which has not been accessed is held.

| Bit      | Bit Name | Initial Value | R/W | Description                                                                      |
|----------|----------|---------------|-----|----------------------------------------------------------------------------------|
| 31 to 21 | —        | 0             | R   | Reserved<br>These bits are always read as 0. The write value should always be 0. |

| Bit | Bit Name | Initial Value | R/W                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----|----------|---------------|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 20  | DI       | 0             | (R/W)* <sup>2</sup> | <p>Direct/Indirect Selection</p> <p>DI selects direct address mode or indirect address mode in channel 3.</p> <p>This bit is only valid in CHCR_3 and is not used in CHCR_0 to CHCR_2. Writing to this bit is invalid in CHCR_0 to CHCR_2; 0 is read if this bit is read. When using 16-byte transfer, direct address mode must be specified. Operation is not guaranteed if indirect address mode is specified.</p> <p>0: Direct address mode<br/>1: Indirect address mode</p>                                                    |
| 19  | RO       | 0             | (R/W)* <sup>2</sup> | <p>Source Address Reload</p> <p>RO selects whether the source address initial value is reloaded in channel 2.</p> <p>This bit is only valid in CHCR_2 and is not used in CHCR_0 to CHCR_1, or CHCR_3. Writing to this bit is invalid in CHCR_0, CHCR_1, and CHCR_3; 0 is read if this bit is read. When using 16-byte transfer, this bit must be cleared to 0, specifying non-reloading. Operation is not guaranteed if reloading is specified.</p> <p>0: A source address is not reloaded<br/>1: A source address is reloaded</p> |
| 18  | RL       | 0             | (R/W)* <sup>2</sup> | <p>Request Check Level</p> <p>RL specifies the DRAK (acknowledge of <math>\overline{DREQ}</math>) signal output is high active or low active.</p> <p>This bit is only valid in CHCR_0 and CHCR_1. Writing to this bit is invalid in CHCR_2 and CHCR_3; 0 is read if this bit is read.</p> <p>0: Low-active output of DRAK<br/>1: High-active output of DRAK</p>                                                                                                                                                                    |
| 17  | AM       | 0             | (R/W)* <sup>2</sup> | <p>Acknowledge Mode</p> <p>AM specifies whether DACK is output in data read cycle or in data write cycle in dual address mode.</p> <p>This bit is only valid in CHCR_0 and CHCR_1. Clearing this bit during transfer can terminate transfer.</p> <p>Even if the DE bit is set, transfer is not enabled if the TE bit is 1, the DME bit in DMAOR is 0, or the NMIF bit in DMAOR is 1.</p>                                                                               |

Notes: 1. Only 0 can be written to the TE bit after 1 is read.  
2. DI, RO, RL, AM, AL, and DS bits are not included in some channels.

### 9.3.5 DMA Operation Register (DMAOR)

The DMA operation register (DMAOR) is a 16-bit read/write register that controls the DMAC transfer mode.

This register's values are initialized to 0s by resets. The previous value is held in standby mode.

| Bit      | Bit Name | Initial Value | R/W    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

Note: \* Only 0 can be written to the AE and NMIF bits after 1 is read.

## 9.4 Operation

When there is a DMA transfer request, the DMAC starts the transfer according to the predetermined channel priority order; when the transfer end conditions are satisfied, it ends the transfer. Transfers can be requested in three modes: auto request, external request, and on-chip peripheral module request. The dual address mode has direct address transfer mode and indirect address transfer mode. In the bus mode, the burst mode or the cycle steal mode can be selected.

### 9.4.1 DMA Transfer Flow

After the DMA source address registers (SAR\_0 to SAR\_3), DMA destination address registers (DAR\_0 to DAR\_3), DMA transfer count registers (DMATCR\_0 to DMATCR\_3), DMA channel control registers (CHCR\_0 to CHCR\_3), and DMA operation register (DMAOR) are set, the DMAC transfers data according to the following procedure:

1. Checks to see if transfer is enabled (DE = 1, DME = 1, TE = 0, AE = 0, NMIF = 0)
2. When a transfer request comes and transfer is enabled, the DMAC transfers 1 transfer unit of data (depending on the TS0 and TS1 settings). For an auto request, the transfer begins automatically when the DE bit and DME bit are set to 1. The DMATCR value will be decremented for each transfer. The actual transfer flows vary by address mode and bus mode.
3. When the specified number of transfer have been completed (when DMATCR reaches 0), the transfer ends normally. If the IE bit of the CHCR is set to 1 at this time, a DEI interrupt is sent to the CPU.
4. When an NMI interrupt is generated or an address error occurs during DMA transfer, the transfers are suspended. Transfers are also suspended when the DE bit of the CHCR or the DME bit of the DMAOR are changed to 0.

Figure 9.2 is a flowchart of this procedure.

- Notes:
1. In auto-request mode, transfer begins when NMIF and TE are all 0 and the DE and DME bits are set to 1.
  2.  $\overline{\text{DREQ}}$  = level detection in burst mode (external request) or cycle-steal mode.
  3.  $\overline{\text{DREQ}}$  = edge detection in burst mode (external request), or auto-request mode in burst mode.

**Figure 9.2 DMAC Transfer Flowchart**

### 9.4.2 DMA Transfer Requests

DMA transfer requests are basically generated in either the data transfer source or destination, but they can also be generated by external devices and on-chip peripheral modules that are neither the source nor the destination. Transfers can be requested in three modes: auto request, external request, and on-chip peripheral module request. The request mode is selected in the RS3 to RS0 bits of CHCR\_0 to CHCR\_3.

**Auto-Request Mode:** When there is no transfer request signal from an external source, as in a memory-to-memory transfer or a transfer between memory and an on-chip peripheral module unable to request a transfer, the auto-request mode allows the DMAC to automatically generate a transfer request signal internally. When the DE bits of CHCR\_0 to CHCR\_3 and the DME bit of the DMAOR are set to 1, the transfer begins so long as the TE bits of CHCR\_0 to CHCR\_3 and the AE but and NMIF bit of DMAOR are all 0.

**External Request Mode:** In this mode a transfer is performed at the request signal ( $\overline{\text{DREQ}}$ ) of an external device. Choose one of the modes shown in table 9.2 according to the application system. When this mode is selected, if the DMA transfer is enabled (DE = 1, DME = 1, TE = 0, AE = 0, NMIF = 0), a transfer is performed upon a request at the  $\overline{\text{DREQ}}$  input. Choose to detect  $\overline{\text{DREQ}}$  by either the falling edge or low level of the signal input with the DS bit of CHCR\_0 to CHCR\_1 (DS = 0 is level detection, DS = 1 is edge detection). The source of the transfer request does not have to be the data transfer source or destination.

**Table 9.2 Selecting External Request Modes with the RS Bits**

| RS3 | RS2 | RS1 | RS0 | Address Mode        | Source                                         | Destination                                    |
|-----|-----|-----|-----|---------------------|------------------------------------------------|------------------------------------------------|
| 0   | 0   | 0   | 0   | Dual address mode   | Any*                                           | Any*                                           |
|     |     | 1   | 0   | Single address mode | External memory, memory-mapped external device | External device with DACK                      |
|     |     |     | 1   |                     | External device with DACK                      | External memory, memory-mapped external device |

Note: \* External memory, memory-mapped external device, on-chip memory, on-chip peripheral module (excluding DMAC, UBC, and BSC)

**On-Chip Peripheral Module Request:** In this mode a transfer is performed at the transfer request signal (interrupt request signal) of an on-chip peripheral module. This mode cannot be set in case of 16-byte transfer. The transfer request signals include 4 signals: the receive data full interrupts (RXI) and the transmit data empty interrupts (TXI) from serial communication interfaces (SCIF), the A/D conversion end interrupt (ADI) of the A/D converter, and the compare match timer interrupt (CMI) of the CMT. When this mode is selected, if the DMA transfer is enabled (DE = 1, DME = 1, TE = 0, AE = 0, NMIF = 0), a transfer is performed upon the input of a transfer request signal. The source of the transfer request does not have to be the data transfer source or destination. When RXI is set as the transfer request, however, the transfer source must be the SCI's receive data register (RDR). Likewise, when TXI is set as the transfer request, the transfer source must be the SCI's transmit data register (TDR). And if the transfer requester is the A/D converter, the data transfer source must be the A/D data register (ADDR).

**Table 9.3 Selecting On-Chip Peripheral Module Request Modes with the RS Bit**

| RS3 | RS2 | RS1 | RS0 | DMA<br>Transfer<br>Request<br>Source | DMA Transfer Request Signal                                   | Source | Desti-<br>nation | Bus Mode              |
|-----|-----|-----|-----|--------------------------------------|---------------------------------------------------------------|--------|------------------|-----------------------|
| 1   | 0   | 1   | 0   |                                      |                                                               |        |                  |                       |
| 1   | 0   | 1   | 1   |                                      |                                                               |        |                  |                       |
| 1   | 1   | 0   | 0   | SCIF<br>transmitter                  | TXI2 (SCIF transmit data empty<br>interrupt transfer request) | Any*   | TDR2             | Burst/<br>cycle steal |
| 1   | 1   | 0   | 1   | SCIF<br>receiver                     | RXI2 (SCIF receive data full<br>interrupt transfer request)   | RDR1   | Any*             | Burst/<br>cycle steal |
| 1   | 1   | 1   | 0   | A/D<br>converter                     | ADI (A/D conversion end<br>interrupt)                         | ADDR   | Any*             | Burst/<br>cycle steal |
| 1   | 1   | 1   | 1   | CMT                                  | CMI (Compare match timer<br>interrupt)                        | Any*   | Any*             | Burst/<br>cycle steal |

ADDR: A/D data register of A/D converter

Note: \* External memory, memory-mapped external device, on-chip peripheral module (excluding DMAC, UBC , and BSC)

When outputting transfer requests from on-chip peripheral modules, the appropriate interrupt enable bits must be set to output the interrupt signals.

If the interrupt request signal of the on-chip peripheral module is used as a DMA transfer request signal, an interrupt is not generated to the CPU.

The DMA transfer request signals of table 9.3 are automatically withdrawn when the corresponding DMA transfer is performed. If the cycle-steal mode is being used, they are withdrawn at the first transfer; if the burst mode is being used, they are withdrawn at the last transfer.

### 9.4.3 Channel Priority

When the DMAC receives simultaneous transfer requests on two or more channels, it selects a channel according to a predetermined priority order. Two modes (fixed mode and round-robin mode) are selected by the priority bits PR1 and PR0 in the DMA operation register (DMAOR).

**Fixed Mode:** In this mode, the priority levels among the channels remain fixed. There are three kinds of fixed modes as follows:

- CH0 > CH1 > CH2 > CH3
- CH0 > CH2 > CH3 > CH1
- CH2 > CH0 > CH1 > CH3

These are selected by the PR1 and the PR0 bits in the DMA operation register (DMAOR).

**Round-Robin Mode:** Each time one word, byte, or longword, or 16-byte data is transferred on one channel, the priority order is rotated. The channel on which the transfer was just finished rotates to the bottom of the priority order. The round-robin mode operation is shown in figure 9.3. The priority of the round-robin mode is CH0 > CH1 > CH2 > CH3 immediately after a reset.

**(1) When channel 0 transfers**

**(2) When channel 1 transfers**

**(3) When channel 2 transfers**

**(4) When channel 3 transfers**

**Figure 9.3 Round-Robin Mode**

Figure 9.4 shows how the priority order changes when channel 0 and channel 3 transfers are requested simultaneously and a channel 1 transfer is requested during the channel 0 transfer. The DMAC operates as follows:

1. Transfer requests are generated simultaneously to channels 0 and 3.
2. Channel 0 has a higher priority, so the channel 0 transfer begins first (channel 3 waits for transfer).
3. A channel 1 transfer request occurs during the channel 0 transfer (channels 1 and 3 are both waiting)
4. When the channel 0 transfer ends, channel 0 becomes lowest priority.
5. At this point, channel 1 has a higher priority than channel 3, so the channel 1 transfer begins (channel 3 waits for transfer).
6. When the channel 1 transfer ends, channel 1 becomes lowest priority.
7. The channel 3 transfer begins.
8. When the channel 3 transfer ends, channels 3 and 2 shift downward in priority so that channel 3 becomes the lowest priority.

**Figure 9.4 Changes in Channel Priority in Round-Robin Mode**

### 9.4.4 DMA Transfer Types

The DMAC supports the transfers shown in table 9.4. The dual address mode has the direct address mode and the indirect address mode. In the direct address mode, an output address value is the data transfer target address; in the indirect address mode, the value stored in the output address, not the output address value itself, is the data transfer target address. A data transfer timing depends on the bus mode, which has cycle steal mode and burst mode.

**Table 9.4 Supported DMA Transfers**

| Source                        | Destination               |                 |                               |                           |
|-------------------------------|---------------------------|-----------------|-------------------------------|---------------------------|
|                               | External Device with DACK | External Memory | Memory-Mapped External Device | On-Chip Peripheral Module |
| External device with DACK     | Not available             | Dual, single    | Dual, single                  | Not available             |
| External memory               | Dual, single              | Dual            | Dual                          | Dual                      |
| Memory-mapped external device | Dual, single              | Dual            | Dual                          | Dual                      |
| On-chip peripheral module     | Not available             | Dual            | Dual                          | Dual                      |

Notes: 1. Dual: Dual address mode  
2. Single: Single address mode  
3. The dual address mode includes the direct address mode and the indirect address mode.  
4. 16-byte transfer is not available for on-chip peripheral modules.

## Address Modes:

- Dual Address Mode

In the dual address mode, both the transfer source and destination are accessed (selectable) by an address. The source and destination can be located externally or internally. The dual address mode has (1) direct address transfer mode and (2) indirect address transfer mode.

(1) In the direct address transfer mode, DMA transfer requires two bus cycles because data is read from the transfer source in a data read cycle and written to the transfer destination in a data write cycle. At this time, transfer data is temporarily stored in the DMAC. In the transfer between external memories as shown in figure 9.5, data is read to the DMAC from one external memory in a data read cycle, and then that data is written to the other external memory in a write cycle. Figures 9.6 to 9.8 show examples of the timing at this time.

The SAR value is an address, data is read from the transfer source module, and the data is temporarily stored in the DMAC.

The DAR value is an address and the value stored in the data buffer in the DMAC is written to the transfer destination module.

Second bus cycle

**Figure 9.5 Operation in the Direct Address Mode in the Dual Address Mode**

Note: Transfer between external memories, DACK output in a read cycle DACK output timing is the same as that of  $\overline{CSn}$ .

**Figure 9.6 Example of DMA Transfer Timing in the Direct Address Mode  
in the Dual Address Mode  
(Transfer Source: Ordinary Memory, Transfer Destination: Ordinary Memory)**

Note: Transfer between external memories, DACK output in a read cycle DACK output timing is the same as that of  $\overline{CSn}$ .

**(16-byte Transfer, Transfer Source: Ordinary Memory, Transfer Destination: Ordinary Memory)**

Note: Transfer between external memories, DACK output in a read cycle DACK output timing is the same as that of  $\overline{CSn}$ .

**Figure 9.8 Example of DMA Transfer Timing in the Direct Address Mode in the Dual Address Mode**  
**(16-byte Transfer, Transfer Source: Synchronous DRAM, Transfer Destination: Ordinary Memory)**

- (2) In the indirect address transfer mode, the address of memory in which data to be transferred is stored is specified in the transfer source address register (SAR\_3) in the DMAC. In this mode, the address value specified in the transfer source address register in the DMAC is read first. This value is temporarily stored in the DMAC. Next, the read value is output as an address, and the value stored in that address is stored in the DMAC again. Then, the value read afterwards is written to the address specified in the transfer destination address; this completes one DMA transfer. 16-byte transfer is not possible. Figure 9.9 shows one example. In this example, the transfer destination, the transfer source, and the storage destination of the indirect address are external memories with a 16-bit width in the indirect address mode, and transfer data is 16 or 8 bits. Figure 9.10 shows an example of the transfer timing.

When the value in SAR\_3 is an address, the memory data is read and the value is stored in the temporary buffer. The value to be read must be 32 bits since it is used for the address.

#### First and second bus cycles

When the value in the temporary buffer is an address, the data is read from the transfer source module to the data buffer.

#### Third bus cycle

When the value in SAR\_3 is an address, the value in the data buffer is written to the transfer source module.

#### Fourth bus cycle

Note: The above description uses the memory, transfer source module, or transfer destination module; in practice, any module can be connected in the addressing space.

**Figure 9.9 Operation in the Indirect Address mode in the Dual Address Mode  
(When the External Memory Space has a 16-bit Width)**

Notes: 1. The internal address bus value does not change, and controlled by the port.  
2. The DMAC does not fetch the value until 32-bit data is output to the internal data bus.

**Figure 9.10 Example of Transfer Timing in the Indirect Address Mode in the Dual Address Mode**

- **Single Address Mode**

In the single address mode, either the transfer source or transfer destination external device is accessed (selected) by means of the DACK signal, and the other device is accessed by address. In this mode, the DMAC performs one DMA transfer in one bus cycle, accessing one of the external devices by outputting the DACK transfer request acknowledge signal to it, and at the same time outputting an address to the other device involved in the transfer. For example, in the case of transfer between external memory and an external device with DACK, as shown in figure 9.11, when the external device outputs data to the data bus, that data is written to the external memory in the same bus cycle.

**Figure 9.11 Data Flow in the Single Address Mode**

Two kinds of transfer are possible in the single address mode: (1) transfer between an external device with DACK and a memory-mapped external device, and (2) transfer between an external device with DACK and external memory. In both cases, only the external request signal (DREQ) is used for transfer requests.

Figures 9.12 to 9.14 show examples of DMA transfer timing in the single address mode.

(a) External device with DACK  $\rightarrow$  external memory space (ordinary memory)

(b) External memory space  $\rightarrow$  external device with DACK (active low)

**Figure 9.12 Example of DMA Transfer Timing in the Single Address Mode**

**Figure 9.13 Example of DMA Transfer Timing in the Single Address Mode**  
**(16- Byte Transfer, External Memory Space (Ordinary Memory) -> External Device with DACK)**

**Bus Modes:** There are two bus modes: cycle-steal and burst. Select the mode in the TM bits of CHCR\_0 to CHCR\_3 (one byte, word, or longword, or 16-byte data).

- **Cycle-Steal Mode**

In the cycle-steal mode, the bus right is given to another bus master after a one-transfer-unit (8-, 16-, or 32-bit unit) DMA transfer. When another transfer request occurs, the bus rights are obtained from the other bus master and a transfer is performed for one transfer unit. When that transfer ends, the bus right is passed to the other bus master. This is repeated until the transfer end conditions are satisfied.

In the cycle-steal mode, transfer areas are not affected regardless of settings of the transfer request source, transfer source, and transfer destination. Figure 9.14 shows an example of DMA transfer timing in the cycle steal mode. Transfer conditions shown in the figure are:

- Dual address mode
- DREQ level detection

**Figure 9.14 DMA Transfer Example in the Cycle-Steal Mode**

- Burst Mode

In the burst mode, once the bus right is obtained, the transfer is performed continuously without passing it until the transfer end conditions are satisfied. In the external request mode with low level detection of the  $\overline{\text{DREQ}}$  pin, however, when the  $\overline{\text{DREQ}}$  pin is driven high, the bus is passed to the other bus master after the DMAC transfer request that has already been accepted ends, even if the transfer end conditions have not been satisfied.

The burst mode cannot be used when the serial communications interface (SCIF) and A/D converter are the transfer request sources. Figure 9.15 shows a timing at this point.

**Figure 9.15 DMA Transfer Example in the Burst Mode**

**Relationship between Request Modes and Bus Modes by DMA Transfer Category:** Table 9.5 shows the relationship between request modes and bus modes by DMA transfer category.

**Table 9.5 Relationship of Request Modes and Bus Modes by DMA Transfer Category**

| Address Mode | Transfer Category                                               | Request Mode      | Bus Mode          | Transfer Size (bits)  | Usable Channels      |
|--------------|-----------------------------------------------------------------|-------------------|-------------------|-----------------------|----------------------|
| Dual         | External device with DACK and external memory                   | External          | B/C               | 8/16/32/128           | 0, 1                 |
|              | External device with DACK and memory-mapped external device     | External          | B/C               | 8/16/32/128           | 0, 1                 |
|              | External memory and external memory                             | All* <sup>1</sup> | B/C               | 8/16/32/128           | 0 to 3* <sup>5</sup> |
|              | External memory and memory-mapped external device               | All* <sup>1</sup> | B/C               | 8/16/32/128           | 0 to 3* <sup>5</sup> |
|              | Memory-mapped external device and memory-mapped external device | All* <sup>1</sup> | B/C               | 8/16/32/128           | 0 to 3* <sup>5</sup> |
|              | External memory and on-chip peripheral module                   | All* <sup>2</sup> | B/C* <sup>3</sup> | 8/16/32* <sup>4</sup> | 0 to 3* <sup>5</sup> |
|              | Memory-mapped external device and on-chip peripheral module     | All* <sup>2</sup> | B/C* <sup>3</sup> | 8/16/32* <sup>4</sup> | 0 to 3* <sup>5</sup> |
|              | On-chip peripheral module and on-chip peripheral module         | All* <sup>2</sup> | B/C* <sup>3</sup> | 8/16/32* <sup>4</sup> | 0 to 3* <sup>5</sup> |

| Address Mode | Transfer Category                                           | Request Mode | Bus Mode | Transfer Size (bits) | Usable Channels |
|--------------|-------------------------------------------------------------|--------------|----------|----------------------|-----------------|
| Single       | External device with DACK and external memory               | External     | B/C      | 8/16/32/128          | 0, 1            |
|              | External device with DACK and memory-mapped external device | External     | B/C      | 8/16/32/128          | 0, 1            |

B: Burst, C: Cycle steal

- Notes:
1. External requests, auto requests and on-chip peripheral module requests are all available. For on-chip peripheral module requests, however, SCIF, and A/D converter cannot be specified as the transfer request source.
  2. External requests, auto requests and on-chip peripheral module requests are all available. When the SCIF, or A/D converter is also the transfer request source, however, the transfer destination or transfer source must be the SCIF, or A/D converter, respectively.
  3. If the transfer request source is the SCIF, the cycle-steal mode is only available.
  4. The access size permitted when the transfer destination or source is an on-chip peripheral module register.
  5. If the transfer request is an external request, channels 0 and 1 are only available.
  6. If the transfer request source is the SDRAM, the transfer size should be set smaller than the bus width.

**Bus Mode and Channel Priority Order:** When a given channel 1 is transferring in the burst mode and there is a transfer request to a channel 0 with a higher priority, the transfer of channel 0 will begin immediately.

At this time, if the priority is set in the fixed mode ( $CH0 > CH1$ ), the channel 1 transfer will continue when the channel 0 transfer has completely finished, even if channel 0 is operating in the cycle-steal mode or in the burst mode.

If the priority is set in the round-robin mode, channel 1 will begin operating again after channel 0 completes the transfer of one transfer unit, even if channel 0 is in the cycle-steal mode or in the burst mode. The bus will then switch between the two in the order channel 1, channel 0, channel 1, channel 0.

Even if the priority is set in the fixed mode or in the round-robin mode, it will not give the bus to the CPU since channel 1 is in the burst mode. This example is illustrated in figure 9.16.

**Figure 9.16 Bus State when Multiple Channels are Operating (Priority Level is Round-robin Mode)**

#### 9.4.5 Number of Bus Cycle States and $\overline{\text{DREQ}}$ Pin Sampling Timing

**Number of Bus Cycle States:** When the DMAC is the bus master, the number of bus cycles is controlled by the bus state controller (BSC) in the same way as when the CPU is the bus master. For details, see section 8, Bus State Controller (BSC).

**$\overline{\text{DREQ}}$  Pin Sampling Timing:** In the external request mode, the  $\overline{\text{DREQ}}$  pin is sampled by clock pulse (CKIO) falling edge or low level detection. When  $\overline{\text{DREQ}}$  input is detected, a DMAC bus cycle is generated and DMA transfer is performed, at the earliest, three states later.

The second and subsequent  $\overline{\text{DREQ}}$  sampling operations are started two cycles after the first sample.

## Operation

- Cycle-Steal Mode

In the cycle-steal mode, the DREQ sampling timing is the same regardless of whether level or edge detection is used.

For example, in figure 9.17 (cycle-steal mode, level detection), DMAC transfer begins, at the earliest, three cycles after the first sampling is performed. The second sampling is started two cycles after the first. If DREQ is not detected at this time, sampling is performed in each subsequent cycle.

Thus, DREQ sampling is performed one step in advance. The third sampling operation is not performed until the idle cycle following the end of the first DMA transfer.

The above conditions are the same whatever the number of CPU transfer cycles, as shown in figure 9.18, and whatever the number of DMA transfer cycles, as shown in figure 9.19.

DACK is output in a read in the example in figure 9.17, and in a write in the example in figure 9.18. In both cases, DACK is output for the same duration as CSn.

Figure 9.20 illustrates the case where DREQ is not detected and sampling is subsequently executed every cycle.

Figure 9.21 shows an example of edge detection in the cycle-steal mode.

- Burst Mode, Level Detection

In the case of burst mode with level detection, the DREQ sampling timing is the same as in the cycle-steal mode.

For example, in figure 9.22, DMAC transfer begins, at the earliest, three cycles after the first sampling is performed. The second sampling is started two cycles after the first. Subsequent sampling operations are performed in the idle cycle following the end of the DMA transfer cycle.

In the burst mode, also, the DACK output period is the same as in the cycle-steal mode.

- Burst Mode, Edge Detection

In the case of burst mode with edge detection,  $\overline{\text{DREQ}}$  sampling is only performed once.

For example, in figure 9.23, DMAC transfer begins, at the earliest, three cycles after the first sampling is performed. After this, DMAC transfer is executed continuously until the number of data transfers set in the DMATCR register have been completed.  $\overline{\text{DREQ}}$  is not sampled during this time.

To restart DMA transfer after it has been suspended by an NMI, first clear NMIF, then input an edge request again.

In the burst mode, also, the DACK output period is the same as in the cycle-steal mode.

**Figure 9.17 Cycle-Steal Mode, Level Input (CPU Access: 2 Cycles)**

**Figure 9.21 Cycle-Steal Mode, Edge input (CPU Access: 2 Cycles)**

**Figure 9.22 Burst Mode, Level Input**

**Figure 9.23 Burst Mode, Edge Input**

## 9.4.6 Source Address Reload Function

Channel 2 includes a reload function, in which the value returns to the value set in the SAR\_2 for each four transfers by setting the RO bit in CHCR\_2 to 1. 16-byte transfer cannot be used. Figure 9.24 shows this operation. Figure 9.25 shows the timing chart of the source address reload function, which is under the following conditions: burst mode, auto request, 16-bit transfer data size, SAR\_2 count-up, DAR\_2 fixed, reload function on, and usage of only channel 2.

**Figure 9.24 Source Address Reload Function Diagram**

**Figure 9.25 Timing Chart of Source Address Reload Function**

Even if the transfer data size is 8, 16, or 32 bits, a reload function can be executed.

DMATCR\_2, which specifies a transfer count, decrements 1 each time a transfer ends regardless of whether a reload function is on or off. Consequently, be sure to specify the value multiple of four in DMATCR\_2 when the reload function is on. Specifying other values does not guarantee the operation.

Though the counters that count transfers of four times for the reload function are reset by clearing the DME bit in DMAOR or the DE bit in CHCR\_2, by setting the transfer end flag (TE bit in CHCR\_2) by a DMAC address error, or by inputting NMI, besides by resets, the SAR\_2, DAR\_2, DMATCR\_2 registers are not reset. Therefore, if these sources are generated, the counters that are initialized and are not initialized exist in the DMAC; malfunction will be caused by restarting the DMAC in that state. Consequently, if these sources occur except for setting the TE bit during the usage of the reload function, set SAR\_2, DAR\_2, and DMATCR\_2 again.

## 9.4.7 DMA Transfer Ending Conditions

The DMA transfer ending conditions vary for individual channels ending and all channels ending together. At transfer end, the following conditions are applied except the case where the value set in the DMATCR reaches 0.

(a) Cycle-steal mode (external request, internal request, and auto request)

When the transfer ending conditions are satisfied, DMAC transfer request acceptance is suspended. The DMAC stops operating after completing the number of transfers that it has accepted until the ending conditions are satisfied.

In the cycle-steal mode, the operation is the same regardless of whether the transfer request is detected by the level or at the edge.

(b) Burst mode, edge detection (external request, internal request, and auto request)

The timing from the point where the ending conditions are satisfied to the point where the DMAC stops operating differs from that in cycle steal mode. In the edge detection in the burst mode, though only one transfer request is generated to start up the DMAC, stop request sampling is performed in the same timing as transfer request sampling in the cycle-steal mode. As a result, the period when stop request is not sampled is regarded as the period when transfer request is generated, and after performing the DMA transfer for this period, the DMAC stops operating.

(c) Burst mode, level detection (external request)

Same as described in (a).

(d) Bus timing when transfers are suspended

The transfer is suspended when one transfer ends. Even if transfer ending conditions are satisfied during read in the direct address transfer in the dual address mode, the subsequent write process is executed, and after the transfer in (a) to (c) above has been executed, DMAC operation suspends.

**Individual Channel Ending Conditions:** There are two ending conditions. A transfer ends when the value of the channel's DMATCR is 0, or when the DE bit of the channel's CHCR is cleared to 0.

- When DMATCR is 0: When the DMATCR value becomes 0 and the corresponding channel's DMA transfer ends, the transfer end flag bit (TE) is set in the CHCR. If the IE (interrupt enable) bit has been set, a DMAC interrupt (DEI) is requested to the CPU. This transfer ending does not apply to conditions in (a) to (d) described above.
- When DE of CHCR is 0: Software can halt a DMA transfer by clearing the DE bit in the channel's CHCR. The TE bit is not set when this happens. This transfer ending does not apply to conditions in (a) to (d) described above.

**Conditions for Ending All Channels Simultaneously:** Transfers on all channels end when 1) the NMIF or AE bit in the DMAOR is set to 1, or 2) when the DME bit in the DMAOR is cleared to 0.

- Transfers ending when the AE bit or NMIF bit is set to 1 in DMAOR: When an NMI interrupt occurs, the AE bit or NMIF bit is set to 1 in the DMAOR and all channels stop their transfers according to the conditions in (a) to (d) described above, and pass the bus right to other bus masters. Consequently, even if the AE bit or NMI bit is set to 1 during transfer, the SAR, DAR, DMATCR are updated. The TE bit is not set. To resume the transfers after DMAC address error exception handling or NMI interrupt exception handling, clear the AE or NMIF bit to 0. At this time, if there are channels that should not be restarted, clear the corresponding DE bit in the CHCR.
- Transfers ending when DME is cleared to 0 in DMAOR: Clearing the DME bit to 0 in the DMAOR forcibly stops the transfers on all channels. The TE bit is not set. All channels stop their transfers according to the conditions in (a) to (d) in 9.4.7, DMA Transfer Ending Condition, as in DMAC address error occurrence or NMI interrupt generation. In this case, the values in SAR, DAR, and DMATCR are also updated.

## 9.5 Compare Match Timer (CMT)

DMAC has an on-chip compare match timer (CMT) to generate DMA transfer request. The CMT has 16-bit counter. Figure 9.26 shows a CMT block diagram.

### 9.5.1 Feature

The CMT has the following features:

- Four types of counter input clock can be selected
  - One of four internal clocks ( $P\phi/4$ ,  $P\phi/8$ ,  $P\phi/16$ ,  $P\phi/64$ ) can be selected.
- Generate DMA transfer request when compare match occurs.

**Figure 9.26 CMT Block Diagram**

## 9.5.2 Register Description

The CMT has the following registers. Refer to section 23, List of Registers, for more details of the addresses and access sizes.

- Compare match timer start register (CMSTR)
- Compare match timer control/status register (CMCSR)
- Compare match counter (CMCNT)
- Compare match constant register (CMCOR)

### • Compare Match Timer Start Register (CMSTR)

The compare match timer start register (CMSTR) is a 16-bit register that selects whether to operate or halt the channel 0 and channel 1 counter (CMCNT).

| Bit     | Bit Name | Initial Value | R/W | Description                                                                                                                                         |
|---------|----------|---------------|-----|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| 15 to 2 | —        | 0             | R   | Reserved<br>These bits are always read as 0. The write value should always be 0.                                                                    |
| 1       | —        | 0             | R/W | Reserved<br>This bit can be read or written. Write 0 when writing.                                                                                  |
| 0       | STR0     | 0             | R/W | Count start 0<br>Selects whether to operate or halt compare match timer counter 0.<br>0: CMCNT0 count operation halted<br>1: CMCNT0 count operation |

### • Compare Match Timer Control/Status Register (CMCSR)

The compare match timer control/status register (CMCSR) is a 16-bit register that indicates the occurrence of compare matches, sets the enable/disable of interrupts, and establishes the clock used for incrementation.

| Bit     | Bit Name | Initial Value | R/W | Description                                                                  |
|---------|----------|---------------|-----|------------------------------------------------------------------------------|
| 15 to 8 | —        | 0             | R   | Reserved<br>These bits always read as 0. The write value should always be 0. |

| Bit    | Bit Name | Initial Value | R/W    | Description                                                                                                                                                                                                                                                                                                                                                                                                |
|--------|----------|---------------|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7      | CMF      | 0             | R/(W)* | <p>Compare match flag</p> <p>This flag indicates whether CMCNT and CMCOR values have matched or not.</p> <p>0: CMCNT and CMCOR values have not matched</p> <p>Clearing condition: Write 0 to CMF after reading CMF = 1</p> <p>1: CMCNT and CMCOR values have matched</p>                                                                                                                                   |
| 6      | —        | 0             | R/W    | <p>Reserved</p> <p>Both read and write are available. The write value should always be 0.</p>                                                                                                                                                                                                                                                                                                              |
| 5 to 2 | —        | 0             | R      | <p>Reserved</p> <p>These bits always read as 0. The write value should always be 0.</p>                                                                                                                                                                                                                                                                                                                    |
| 1      | CKS1     | 0             | R/W    | Clock select 1 and 0                                                                                                                                                                                                                                                                                                                                                                                       |
| 0      | CKS0     | 0             | R/W    | <p>These bits select the clock input to the CMCNT from among the four internal clocks obtained by dividing the system clock (<math>P\phi</math>). When the STR bit of the CMSTR is set to 1, the CMCNT begins incrementing with the clock selected by CKS1 and CKS0.</p> <p>00: <math>P\phi/4</math></p> <p>01: <math>P\phi/8</math></p> <p>10: <math>P\phi/16</math></p> <p>11: <math>P\phi/64</math></p> |

Note: \* The only value that can be written is 0 to clear the flag.

### • Compare Match Counter (CMCNT)

The compare match counter (CMCNT) is a 16-bit register used as an up-counter.

When an internal clock is selected with the CKS1 and CKS0 bits of the CMCSR and the STR bit of the CMSTR is set to 1, the CMCNT begins incrementing with the selected clock. When the CMCNT value matches that of the CMCOR, the CMCNT is cleared to H'0000 and the CMF flag of the CMCSR is set to 1.

The CMCNT0 is initialized to H'0000 by resets. It retains its previous value in standby mode.

### • Compare Match Constant Register (CMCOR)

The compare match constant register (CMCOR) is a 16-bit register that sets the compare match period with the CMCNT.

The CMCOR is initialized to H'FFFF by resets. It retains its previous value in standby mode.

### 9.5.3 Operation

#### • Period Count Operation

When an internal clock is selected with the CKS1 and CKS0 bits of the CMCSR register and the STR bit of the CMSTR is set to 1, the CMCNT begins incrementing with the selected clock. When the CMCNT counter value matches that of the CMCOR, the CMCNT counter is cleared to H'0000 and the CMF flag of the CMCSR register is set to 1. The CMCNT counter begins counting up again from H'0000.

Figure 9.27 shows the compare match counter operation.

**Figure 9.27 Counter Operation**

#### • CMCNT Count Timing

One of four clocks ( $P\phi/4$ ,  $P\phi/8$ ,  $P\phi/16$ ,  $P\phi/64$ ) obtained by dividing the the system clock ( $P\phi$ ) can be selected by the CKS1 and CKS0 bits of the CMCSR. Figure 9.28 shows the timing.

**Figure 9.28 Count Timing**

- **Compare Match Flag Set Timing**

The CMF bit of the CMCSR register is set to 1 by the compare match signal generated when the CMCOR register and the CMCNT counter match. The compare match signal is generated upon the final state of the match (timing at which the CMCNT counter matching count value is updated). Consequently, after the CMCOR register and the CMCNT counter match, a compare match signal will not be generated until a CMCNT counter input clock occurs. Figure 9.29 shows the CMF bit set timing.

**Figure 9.29 CMF Set Timing**

- **Compare Match Flag Clear Timing**

The CMF bit of the CMCSR register is cleared by writing 0 to it after reading 1. Figure 9.30 shows the timing when the CMF bit is cleared by the CPU.

**Figure 9.30 Timing of CMF Clear by the CPU**

## 9.6 Examples of Use

### 9.6.1 Example of DMA Transfer between A/D Converter and External Memory (Address Reload on)

In this example, DMA transfer is performed between the on-chip A/D converter (transfer source) and the external memory (transfer destination) with address reload function on. Table 9.6 shows the transfer conditions and register settings.

**Table 9.6 Transfer Conditions and Register Settings for Transfer between On-Chip A/D converter and External Memory**

| Transfer Conditions                            | Register | Setting    |
|------------------------------------------------|----------|------------|
| Transfer source: on-chip A/D converter         | SAR_2    | H'04000080 |
| Transfer destination: external memory          | DAR_2    | H'00400000 |
| Number of transfers: 128 (reloading 32 times)  | DMATCR_2 | H'00000080 |
| Transfer source address: incremented           | CHCR_2   | H'00089E35 |
| Transfer destination address: decremented      |          |            |
| Transfer request source: A/D converter         |          |            |
| Bus mode: burst                                |          |            |
| Transfer unit: long word                       |          |            |
| Interrupt request generated at end of transfer |          |            |
| Channel priority order: 0 > 2 > 3 > 1          | DMAOR    | H'0101     |

When the address reload function is on, the values set in SAR\_0 to SAR\_3 returns to the initially set value at each four transfers. In this example, when an interrupt request is generated from A/D converter, longword data is read from the register in address H'04000080 in A/D converter, and it is written to external memory address H'00400000. Since longword data has been transferred, the values in SAR\_2 and DAR\_2 are H'04000084 and H'003FFFFC, respectively. The bus right is maintained and data transfers are successively performed because this transfer is in the burst mode.

After four transfers end, fifth and sixth transfers are performed if the address reload function is off, and the value in SAR\_2 is incremented from H'0400008C, H'04000090, H'04000094,.... If the address reload function is on, the DMA transfer stops after the fourth transfer ends, the bus request signal to the CPU is cleared. At this time, the value stored in SAR\_2 is not incremented from H'0400008C to H'04000090, but returns to the initially set value H'04000080. The value in DAR\_2 continues being decremented regardless of whether the address reload function is on or off.

As a result, the values in the DMAC are as shown in table 9.7 when the fourth transfer ends, depending on whether the address reload function is on or off.

**Table 9.7 Values in the DMAC after the Fourth Transfer Ends**

| Items                              | Address reload on | Address reload off |
|------------------------------------|-------------------|--------------------|
| SAR_2                              | H'04000080        | H'04000090         |
| DAR_2                              | H'003FFFFC        | H'003FFFFC         |
| DMATCR_2                           | H'0000007C        | H'0000007C         |
| Bus right                          | Released          | Held               |
| DMAC operation                     | Stops             | Keeps operating    |
| Interrupt                          | Not generated     | Not generated      |
| Transfer request source flag clear | Executed          | Not executed       |

- Notes:
1. An interrupt is generated regardless of whether the address reload function is on or off, if transfers are executed until the value in DMATCR\_2 reaches 0 and the IE bit in CHCR\_2 has been set to 1.
  2. The transfer request source flag is cleared regardless of whether the address reload function is on or off, if transfers are executed until the value in DMATCR\_2 reaches 0.
  3. Specify the burst mode to use the address reload function. This function may not be correctly executed in the cycle steal mode.
  4. Set the value multiple of four in DMATCR\_2 to use the address reload function. This function may not be correctly executed if other values are specified.

### 9.6.2 Example of DMA Transfer between External Memory and SCIF Transmitter (Indirect Address on)

In this example, DMA transfer is performed between the external memory specified with the indirect address (transfer source) and the SCIF transmitter (transfer destination) using DMAC channel 3. Table 9.8 shows the transfer conditions and register settings. In addition, the trigger of the number of transmit FIFO data is set to 1 (TTRG1 = TTRG0 = 1 in SCFCR).

**Table 9.8 Transfer Conditions and Register Settings for Transfer between External Memory and SCIF Transmitter**

| Transfer Conditions                               | Register | Setting    |
|---------------------------------------------------|----------|------------|
| Transfer source: external memory                  | SAR_3    | H'00400000 |
| Value stored in address H'00400000                | —        | H'00450000 |
| Value stored in address H'04500000                | —        | H'55       |
| Transfer destination: On-chip SCIF TDR2           | DAR_3    | H'04000156 |
| Number of transfers: 10                           | DMATCR_3 | H'0000000A |
| Transfer source address: incremented              | CHCR_3   | H'00011C01 |
| Transfer destination address: fixed               |          |            |
| Transfer request source: SCIF (TXI2)              |          |            |
| Bus mode: cycle steal                             |          |            |
| Transfer unit: byte                               |          |            |
| No interrupt request generated at end of transfer |          |            |
| Channel priority order: 0 > 1 > 2 > 3             | DMAOR    | H'0001     |

If the indirect address is on, data stored in the address set in SAR\_0 to SAR\_3 is not used as transfer source data. In the indirect address, after the value stored in the address set in SAR\_0 to SAR\_3 is read, that read value is used as an address again, and the value stored in that address is read and stored in the corresponding address set in DAR\_0 to DAR\_3.

In the example shown in table 9.3, when an SCIF transfer request is generated, the DMAC reads the value in address H'00400000 set in SAR\_3. Since the value H'00450000 is stored in that address, the DMAC reads the value H'00450000. Next, the DMAC uses that read value as an address again, and reads the value H'55 stored in that address. Then, the DMAC writes the value H'55 to address H'04000156 set in DAR\_3; this completes one indirect address transfer.

In the indirect address, when data is read first from the address set in SAR\_3, the data transfer size is always longword regardless of the settings of the TS0 and the TS1 bits that specify the transfer data size. However, whether the transfer source address is fixed, incremented, or decremented is specified according to the SM0 and the SM1 bits. Therefore, in this example, though the transfer data size is specified as byte, the value in SAR\_3 is H'00400004 when one transfer ends. Write operation is the same as that in the normal dual address transfer.

## 9.7 Cautions

1. CHCR\_0 to CHCR\_3 can be accessed in any data size. The DMA operation register (DMAOR) must be accessed in byte (eight bits) or word (16 bits); other registers must be accessed in word (16 bits) or longword (32 bits).
2. Before rewriting the RS0 to RS3 bits of CHCR\_0 to CHCR\_3, first clear the DE bit to 0 (when rewriting CHCR, be sure to clear the DE bit to 0 in advance).
3. Even when the NMI interrupt is input when the DMAC is not operating, the NMIF bit of the DMAOR will be set.
4. When entering the standby mode, the DME bit in DMAOR must be cleared to 0 and the transfers accepted by the DMAC must end.
5. The on-chip peripherals which DMAC can access are SCIF, A/D converter, D/A converter, and I/O ports. Do not access the other peripherals by DMAC.
6. When starting up the DMAC, set CHCR\_0 –CHCR\_3 or DMAOR last. Specifying other registers last does not guarantee normal operation.
7. Even if the maximum number of transfers is performed in the same channel after the DMATCR\_0 to DMATCR\_3 count reaches 0 and the DMA transfer ends normally, write 0 to DMATCR\_0–DMATCR\_3. Otherwise, normal DMA transfer may not be performed.
8. When using the address reload function, specify the burst mode as a transfer mode. In the cycle-steal mode, normal DMA transfer may not be performed.
9. When using the address reload function, set the value multiple of four in DMATCR\_0 to DMATCR\_3. Specifying other values does not guarantee normal operation.
10. When detecting an external request at the falling edge, keep the external request pin high when setting the DMAC.
11. Do not access the space ranging from H'4000062 to H'400006F, which is not used in the DMAC. Accessing that space may cause malfunctions.
12. The  $\overline{\text{WAIT}}$  signal is ignored in the following cases:
  - A. In 16-byte DMA transfer or dual addressing mode, or when writing data to the external address area
  - B. In 16-byte DMA transfer or single addressing mode, or when transferring data from an external device with DACK to the external address area

## Section 10 Clock Pulse Generator (CPG)

The clock pulse generator (CPG) supplies all clocks to the processor and controls the power-down modes. A block diagram of the clock pulse generator is shown in figure 10.1.

### 10.1 Feature

The CPG has the following features:

- Four clock modes: Selection of 4 clock modes for different frequency ranges, power consumption, direct crystal input, and external clock input are available.
- Three clocks generated independently: An internal clock for the CPU, cache, and TLB ( $I\phi$ ); a peripheral clock ( $P\phi$ ) for the on-chip supporting modules; and a bus clock ( $CKIO$ ) for the external bus interface.
- Frequency change function: Internal and peripheral clock frequencies can be changed independently using the PLL circuit and divider circuit within the CPG. Frequencies are changed by software using frequency control register (FRQCR) settings.
- Power-down mode control: The clock can be stopped for sleep mode and software standby mode and specific modules can be stopped using the module standby function.

**Figure 10.1 Block Diagram of Clock Pulse Generator**

The clock pulse generator blocks function as follows:

1. PLL Circuit 1: PLL circuit 1 doubles, triples, quadruples, or leaves unchanged the input clock frequency from the CKIO terminal. The multiplication rate is set by the frequency control register. When this is done, the phase of the leading edge of the internal clock ( $I\phi$ ,  $B\phi$ ,  $P\phi$ ) is controlled so that it will agree with the phase of the leading edge of the CKIO pin.
2. PLL Circuit 2: PLL circuit 2 leaves unchanged or quadruples the frequency of the crystal oscillator or the input clock frequency coming from the EXTAL pin. The multiplication ratio is fixed by the clock operation mode. The clock operation mode is set by pins MD0, MD1, and MD2. See table 10.3 for more information on clock operation modes.
3. Crystal Oscillator: This oscillator is used when a crystal oscillator element is connected to the XTAL and EXTAL pins. It operates according to the clock operating mode setting.
4. Divider 1: Divider 1 generates a clock at the operating frequency used by the internal clock. The operating frequency can be 1, 1/2, 1/3, or 1/4 times the output frequency of PLL circuit 1, as long as it stays at or above the clock frequency of the CKIO pin. The division ratio is set in the frequency control register.
5. Divider 2: Divider 2 generates a clock at the operating frequency used by the bus clock ( $B\phi$ ) and peripheral clock ( $P\phi$ ). The operating frequencies can be 1, 1/2, 1/3, 1/4, or 1/6 times the output frequency of PLL Circuit 1 or the clock frequency of the CKIO pin, as long as it stays at or below the clock frequency of the CKIO pin. The division ratio is set in the frequency control register.
6. Clock Frequency Control Circuit: The clock frequency control circuit controls the clock frequency using the MD2–MD0 pins and the frequency control register.
7. Standby Control Circuit: The standby control circuit controls the state of the clock pulse generator and other modules during clock switching and sleep/standby modes.
8. Frequency Control Register: The frequency control register has control bits assigned for the following functions: clock output/non-output from the CKIO pin, on/off control of PLL circuit 1, PLL standby, the frequency multiplication ratio of PLL 1, and the frequency division ratio of the internal clock and the peripheral clock.
9. Standby Control Register: The standby control register has bits for controlling the power-down modes. See section 22, Power-Down Modes, for more information.

## 10.2 Input/Output Pin

Table 10.1 lists the CPG pins and their functions.

**Table 10.1 Clock Pulse Generator Pins and Functions**

| Pin Name                            | Symbol | I/O | Description                                                                |
|-------------------------------------|--------|-----|----------------------------------------------------------------------------|
| Mode control pins                   | MD0    | I   | Set the clock operating mode.                                              |
|                                     | MD1    | I   |                                                                            |
|                                     | MD2    | I   |                                                                            |
| Crystal I/O pins (clock input pins) | XTAL   | O   | Connects a crystal oscillator.                                             |
|                                     | EXTAL  | I   | Connects a crystal oscillator. Also used to input an external clock.       |
| Clock I/O pin                       | CKIO   | I/O | Inputs or outputs an external clock.                                       |
| Capacitor connection pins for PLL   | CAP1   | I   | Connects capacitor for PLL circuit 1 operation (recommended value 470 pF). |
|                                     | CAP2   | I   | Connects capacitor for PLL circuit 2 operation (recommended value 470 pF). |

## 10.3 Clock Operating Modes

Table 10.2 shows the relationship between the mode control pin (MD2 to MD0) combinations and the clock operating modes. Table 10.3 shows the usable frequency ranges in the clock operating modes and frequency ranges of the input clock (crystal oscillation).

**Table 10.2 Clock Operating Modes**

| Mode | Pin Values           |     |     | Clock I/O                   |        | PLL2<br>On/Off                 | PLL1<br>On/Off | Divider 1<br>Input | Divider 2<br>Input | CKIO<br>Frequency |
|------|----------------------|-----|-----|-----------------------------|--------|--------------------------------|----------------|--------------------|--------------------|-------------------|
|      | MD2                  | MD1 | MD0 | Source                      | Output |                                |                |                    |                    |                   |
| 0    | 0                    | 0   | 0   | EXTAL                       | CKIO   | On,<br>multiplication ratio: 1 | On             | PLL1 output        | PLL1               | (EXTAL)           |
| 1    | 0                    | 0   | 1   | EXTAL                       | CKIO   | On,<br>multiplication ratio: 4 | On             | PLL1 output        | PLL1               | (EXTAL) × 4       |
| 2    | 0                    | 1   | 0   | Crystal oscillator          | CKIO   | On,<br>multiplication ratio: 4 | On             | PLL1 output        | PLL1               | (Crystal) × 4     |
| 7    | 1                    | 1   | 1   | CKIO                        | —      | Off                            | On             | PLL1 output        | PLL1               | (CKIO)            |
| —    | Other than the above |     |     | Reserved (setting disabled) |        |                                |                |                    |                    |                   |

**Mode 0:** An external clock is input from the EXTAL pin and undergoes waveform shaping by PLL circuit 2 before being supplied inside this LSI. The frequency ratio between EXTAL input clock and CKIO output clock is 1:1. An input clock frequency of 25 MHz to 66.67 MHz can be used, and the CKIO frequency range is 25 MHz to 66.67 MHz.

**Mode 1:** An external clock is input from the EXTAL pin and its frequency is multiplied by 4 by PLL circuit 2 before being supplied inside this LSI, allowing a low-frequency external clock to be used. The frequency ratio between EXTAL input clock and CKIO output clock is 1:4. An input clock frequency of 6.25 MHz to 16.67 MHz can be used, and the CKIO frequency range is 25 MHz to 66.67 MHz.

**Mode 2:** The on-chip crystal oscillator operates, with the oscillation frequency being multiplied by 4 by PLL circuit 2 before being supplied inside this LSI, allowing a low crystal frequency to be used. The frequency ratio between crystal oscillation and CKIO output clock is 1:4. A crystal oscillation frequency of 6.25 MHz to 16.67 MHz can be used, and the CKIO frequency range is 25 MHz to 66.67 MHz.

**Mode 7:** In this mode, the CKIO pin is an input, an external clock is input to this pin, and undergoes waveform shaping, and also frequency multiplication according to the setting, by PLL circuit 1 before being supplied to this LSI. In modes 0 to 2, the system clock is generated from the output of this LSI's CKIO pin. Consequently, if a large number of ICs are operating synchronized with the clock, the CKIO pin load will be large. This mode, however, assumes a comparatively large-scale system. If a large number of ICs are operating on the clock cycle, a clock generator with a number of low-skew clock outputs can be provided, so that the ICs can operate synchronously by distributing the clocks to each one.

As PLL circuit 1 compensates for fluctuations in the CKIO pin load, this mode is suitable for connection of synchronous DRAM.

**Table 10.3 Available Combination of Clock Mode and FRQCR Values**

| Clock Mode | FRQCR  | PLL1     | PLL2     | Clock Rate* (I:B:P) | Input Frequency Range | CKIO Frequency Range |
|------------|--------|----------|----------|---------------------|-----------------------|----------------------|
| 0          | H'0100 | ON (× 1) | ON (× 1) | 1:1:1               | 25 MHz to 33.34 MHz   | 25 MHz to 33.34 MHz  |
|            | H'0101 | ON (× 1) | ON (× 1) | 1:1:1/2             | 25 MHz to 66.67 MHz   | 25 MHz to 66.67 MHz  |
|            | H'0102 | ON (× 1) | ON (× 1) | 1:1:1/4             | 25 MHz to 66.67 MHz   | 25 MHz to 66.67 MHz  |
|            | H'0111 | ON (× 2) | ON (× 1) | 2:1:1               | 25 MHz to 33.34 MHz   | 25 MHz to 33.34 MHz  |
|            | H'0112 | ON (× 2) | ON (× 1) | 2:1:1/2             | 25 MHz to 66.67 MHz   | 25 MHz to 66.67 MHz  |
|            | H'0115 | ON (× 2) | ON (× 1) | 1:1:1               | 25 MHz to 33.34 MHz   | 25 MHz to 33.34 MHz  |
|            | H'0116 | ON (× 2) | ON (× 1) | 1:1:1/2             | 25 MHz to 66.67 MHz   | 25 MHz to 66.67 MHz  |
|            | H'0122 | ON (× 4) | ON (× 1) | 4:1:1               | 25 MHz to 33.34 MHz   | 25 MHz to 33.34 MHz  |
|            | H'0126 | ON (× 4) | ON (× 1) | 2:1:1               | 25 MHz to 33.34 MHz   | 25 MHz to 33.34 MHz  |
|            | H'012A | ON (× 4) | ON (× 1) | 1:1:1               | 25 MHz to 33.34 MHz   | 25 MHz to 33.34 MHz  |
|            | H'A100 | ON (× 3) | ON (× 1) | 3:1:1               | 25 MHz to 33.34 MHz   | 25 MHz to 33.34 MHz  |
|            | H'A101 | ON (× 3) | ON (× 1) | 3:1:1/2             | 25 MHz to 44.44 MHz   | 25 MHz to 44.44 MHz  |
|            | H'E100 | ON (× 3) | ON (× 1) | 1:1:1               | 25 MHz to 33.34 MHz   | 25 MHz to 33.34 MHz  |
|            | H'E101 | ON (× 3) | ON (× 1) | 1:1:1/2             | 25 MHz to 44.44 MHz   | 25 MHz to 44.44 MHz  |
| 1, 2       | H'0100 | ON (× 1) | ON (× 4) | 4:4:4               | 6.25 MHz to 8.34 MHz  | 25 MHz to 33.34 MHz  |
|            | H'0101 | ON (× 1) | ON (× 4) | 4:4:2               | 6.25 MHz to 16.67 MHz | 25 MHz to 66.67 MHz  |
|            | H'0102 | ON (× 1) | ON (× 4) | 4:4:1               | 6.25 MHz to 16.67 MHz | 25 MHz to 66.67 MHz  |
|            | H'0111 | ON (× 2) | ON (× 4) | 8:4:4               | 6.25 MHz to 8.34 MHz  | 25 MHz to 33.34 MHz  |
|            | H'0112 | ON (× 2) | ON (× 4) | 8:4:2               | 6.25 MHz to 16.67 MHz | 25 MHz to 66.67 MHz  |
|            | H'0115 | ON (× 2) | ON (× 4) | 4:4:4               | 6.25 MHz to 8.34 MHz  | 25 MHz to 33.34 MHz  |
|            | H'0116 | ON (× 2) | ON (× 4) | 4:4:2               | 6.25 MHz to 16.67 MHz | 25 MHz to 66.67 MHz  |
|            | H'0122 | ON (× 4) | ON (× 4) | 16:4:4              | 6.25 MHz to 8.34 MHz  | 25 MHz to 33.34 MHz  |
|            | H'0126 | ON (× 4) | ON (× 4) | 8:4:4               | 6.25 MHz to 8.34 MHz  | 25 MHz to 33.34 MHz  |
|            | H'012A | ON (× 4) | ON (× 4) | 4:4:4               | 6.25 MHz to 8.34 MHz  | 25 MHz to 33.34 MHz  |
|            | H'A100 | ON (× 3) | ON (× 4) | 12:4:4              | 6.25 MHz to 8.34 MHz  | 25 MHz to 33.34 MHz  |

|            | H'E100 | ON (× 3) | ON (× 4) | 4:4:4               | 6.25 MHz to 8.34 MHz  | 25 MHz to 33.34 MHz  |
|            | H'E101 | ON (× 3) | ON (× 4) | 4:4:2               | 6.25 MHz to 11.11 MHz | 25 MHz to 44.44 MHz  |

| Clock Mode | FRQCR  | PLL1              | PLL2 | Clock Rate*<br>(I:B:P) | Input Frequency Range | CKIO Frequency Range |
|------------|--------|-------------------|------|------------------------|-----------------------|----------------------|
| 7          | H'0100 | ON ( $\times 1$ ) | OFF  | 1:1:1                  | 25 MHz to 33.34 MHz   | 25 MHz to 33.34 MHz  |
|            | H'0101 | ON ( $\times 1$ ) | OFF  | 1:1:1/2                | 25 MHz to 66.67 MHz   | 25 MHz to 66.67 MHz  |
|            | H'0102 | ON ( $\times 1$ ) | OFF  | 1:1:1/4                | 25 MHz to 66.67 MHz   | 25 MHz to 66.67 MHz  |
|            | H'0111 | ON ( $\times 2$ ) | OFF  | 2:1:1                  | 25 MHz to 33.34 MHz   | 25 MHz to 33.34 MHz  |
|            | H'0112 | ON ( $\times 2$ ) | OFF  | 2:1:1/2                | 25 MHz to 66.67 MHz   | 25 MHz to 66.67 MHz  |
|            | H'0115 | ON ( $\times 2$ ) | OFF  | 1:1:1                  | 25 MHz to 33.34 MHz   | 25 MHz to 33.34 MHz  |
|            | H'0116 | ON ( $\times 2$ ) | OFF  | 1:1:1/2                | 25 MHz to 66.67 MHz   | 25 MHz to 66.67 MHz  |
|            | H'0122 | ON ( $\times 4$ ) | OFF  | 4:1:1                  | 25 MHz to 33.34 MHz   | 25 MHz to 33.34 MHz  |
|            | H'0126 | ON ( $\times 4$ ) | OFF  | 2:1:1                  | 25 MHz to 33.34 MHz   | 25 MHz to 33.34 MHz  |
|            | H'012A | ON ( $\times 4$ ) | OFF  | 1:1:1                  | 25 MHz to 33.34 MHz   | 25 MHz to 33.34 MHz  |
|            | H'A100 | ON ( $\times 3$ ) | OFF  | 3:1:1                  | 25 MHz to 33.34 MHz   | 25 MHz to 33.34 MHz  |
|            | H'A101 | ON ( $\times 3$ ) | OFF  | 3:1:1/2                | 25 MHz to 44.44 MHz   | 25 MHz to 44.44 MHz  |
|            | H'E100 | ON ( $\times 3$ ) | OFF  | 1:1:1                  | 25 MHz to 33.34 MHz   | 25 MHz to 33.34 MHz  |
|            | H'E101 | ON ( $\times 3$ ) | OFF  | 1:1:1/2                | 25 MHz to 44.44 MHz   | 25 MHz to 44.44 MHz  |

Note: \* Taking input clock as 1

Max. frequency:  $I\phi = 133.34$  MHz,  $B\phi$  (CKIO) = 66.67 MHz,  $P\phi = 33.34$  MHz

### Cautions:

- The input to divider 1 is the output of the PLL circuit 1:
  - When PLL circuit 1 is on.
- The input of divider 2 is the output of the PLL circuit 1:
- The frequency of the internal clock ( $I\phi$ ) is:
  - The product of the frequency of the CKIO pin, the frequency multiplication ratio of PLL circuit 1, and the division ratio of divider 1 when PLL circuit 1 is on.
  - Do not set the internal clock frequency lower than the CKIO pin frequency.
- The frequency of the peripheral clock ( $P\phi$ ) becomes:
  - The product of the frequency of the CKIO pin, the frequency multiplication ratio of PLL circuit 1, and the division ratio of divider 2 when the clock operating mode is 0 to 2 or 7.
  - The peripheral clock frequency should not be set higher than the frequency of the CKIO pin, higher than 33 MHz, or lower than 1/8 the internal clock ( $I\phi$ ).
- The output frequency of PLL circuit 1 is the product of the CKIO frequency and the multiplication ratio of PLL circuit 1.
- $\times 1$ ,  $\times 2$ ,  $\times 3$ , or  $\times 4$  can be used as the multiplication ratio of PLL circuit 1.  $\times 1$ ,  $\times 1/2$ ,  $\times 1/3$ , and  $\times 1/4$  can be selected as the division ratios of dividers 1 and 2. Set the rate in the frequency control register. The on/off state of PLL circuit 2 and the multiplication ratio are determined by the mode.

## 10.4 Register Description

The CPG includes the following register. Refer to section 23, List of Registers, for more details of the addresses and access sizes.

- Frequency control register (FRQCR)

### 10.4.1 Frequency Control Register (FRQCR)

The frequency control register (FRQCR) is a 16-bit read/write register used to specify, the frequency multiplication ratio of PLL circuit 1, and the frequency division ratio of the internal clock and the peripheral clock. Only word access can be used on the FRQCR register.

The FRQCR register is initialized to H'0102 at a power-on reset by the  $\overline{\text{RESETP}}$  pin and retains its previous value at a manual reset or in standby mode.

| Bit | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                                                                                                                                                                       |

Note: Take enough care because the positions of the bits are not continuous.

## 10.5 Operation

The frequency of the internal clock and peripheral clock can be changed either by changing the multiplication rate of PLL circuit 1 or by changing the division rates of dividers 1 and 2. All of these are controlled by software through the frequency control register. The methods are described below.

### 10.5.1 Changing the Multiplication Rate

A PLL settling time is required when the multiplication rate of PLL circuit 1 is changed. The on-chip WDT counts the settling time. Refer the section 11, Watch Dog Timer (WDT) for more details.

1. In the initial state, the multiplication rate of PLL circuit 1 is 1.
2. Set a value that will become the specified oscillation settling time in the WDT and stop the WDT. The following must be set:  
WTCSR register TME bit = 0: WDT stops  
WTCSR register CKS2 to CKS0 bits: Division ratio of WDT count clock  
WTCNT counter: Initial counter value
3. Set the desired value in the STC2, STC1 and STC0 bits. The division ratio can also be set in the IFC2 to IFC0 bits and PFC2 to PFC0 bits.
4. The processor pauses internally and the WDT starts incrementing. At this time, the internal ( $I\phi$ ) and peripheral clocks ( $P\phi$ ) both stop, and the clock is continuously output to the CKIO pin in clock modes 0 to 2.
5. Supply of the clock that has been set begins at WDT count overflow, and the processor begins operating again. The WDT stops after it overflows.

### 10.5.2 Changing the Division Ratio

The WDT will not count unless the multiplication rate is changed simultaneously.

1. In the initial state, IFC2–IFC0 = 000 and PFC2–PFC0 = 010.
2. Set the IFC2, IFC1, IFC0, PFC2, PFC1, and PFC0 bits to the new division ratio. The values that can be set are limited by the clock mode and the multiplication rate of PLL circuit 1. Note that if the wrong value is set, the processor will malfunction.
3. The clock is immediately supplied at the new division ratio.

## 10.6 Usage Note

**When Using an External Crystal Oscillator:** Place the crystal oscillator, capacitors CL1 and CL2, close to the EXTAL and XTAL pins. To prevent induction from interfering with correct oscillation, use a common grounding point for the capacitors connected to the oscillator, and do not locate a wiring pattern near these components.

**Figure 10.2 Points for Attention when Using Crystal Oscillator**

**Decoupling Capacitors:** As far as possible, insert a laminated ceramic capacitor of 0.1 to 1  $\mu\text{F}$  as a passive capacitor for each  $V_{\text{ss}}/V_{\text{cc}}$  pair. Mount the passive capacitors as close as possible to the SH7706 power supply pins, and use components with a frequency characteristic suitable for the chip's operating frequency, as well as a suitable capacitance value.

Digital system  $V_{\text{ss}}/V_{\text{cc}}$  pairs: 11 to 13, 19 to 21, 25 to 27, 37 to 39, 49 to 51, 61 to 63, 84 to 86, 93 to 95, 115 to 117, 137 to 139, 148 to 150, 156 to 158

On-chip oscillator  $V_{\text{ss}}/V_{\text{cc}}$  pairs: 1 to 4, 123 to 125, 126 to 128

**When Using a PLL Oscillator Circuit:** Keep the wiring from the PLL  $V_{\text{cc}}$  and  $V_{\text{ss}}$  connection pattern to the power supply pins short, and make the pattern width large, to minimize the inductance component. Ground the oscillation stabilization capacitors C1 and C2 to  $V_{\text{ss}}$  (PLL1) and  $V_{\text{ss}}$  (PLL2), respectively. Place C1 and C2 close to the CAP1 and CAP2 pins and do not locate a wiring pattern in the vicinity. In clock mode 7, connect the EXTAL pin to  $V_{\text{cc}}Q$  or  $V_{\text{ss}}$  and leave the XTAL pin open.

**Figure 10.3 Points for Attention when Using PLL Oscillator Circuit**

**Notes on Wiring Power Supply Pins:** To avoid crossing signal lines, wire  $V_{CC}$ -PLL1,  $V_{CC}$ -PLL2, and  $V_{SS}$ -PLL2 as three patterns from the power supply source on the board so that they are independent of digital  $V_{CC}$  and  $V_{SS}$ .

# Section 11 Watchdog Timer (WDT)

The WDT is a single-channel timer that counts the clock settling time and is used when clearing software standby mode and temporary standbys, such as frequency changes. It can also be used as an ordinary watchdog timer or interval timer.

Figure 11.1 shows a block diagram of the WDT.

**Figure 11.1 Block Diagram of the WDT**

## 11.1 Feature

The WDT has the following features:

- Can be used to ensure the clock settling time: Use the WDT to cancel software standby mode and the temporary standbys that occur when the clock frequency is changed.
- Can switch between watchdog timer mode and interval timer mode.
- Generates internal resets in watchdog timer mode: Internal resets occur after counter overflow. Selection of power-on reset or manual reset.
- Generates interrupts in interval timer mode: Internal timer interrupts occur after counter overflow.
- Selection of eight counter input clocks. Eight clocks ( $\times 1$  to  $\times 1/4096$ ) can be obtained by dividing the peripheral clock.

## 11.2 Register Description

The WDT has two registers that select the clock, switch the timer mode, and perform other functions. Refer to section 23, List of Registers, for more details of the addresses and access sizes.

- Watchdog timer counter (WTCNT)
- Watchdog timer control/status register (WTCSR)

### 11.2.1 Watchdog Timer Counter (WTCNT)

The watchdog timer counter (WTCNT) is an 8-bit read/write register that increments on the selected clock. When an overflow occurs, it generates a reset in watchdog timer mode and an interrupt in interval time mode. The WTCNT is initialized to H'00 only by a power-on reset through the  $\overline{\text{RESET}}$  pin. Use a word access to write to the WTCNT, with H'5A in the upper byte. Use a byte access to read WTCNT.

| Bit    | Bit Name | Initial Value | R/W | Description   |
|--------|----------|---------------|-----|---------------|
| 7 to 0 | —        | 0             | R/W | 8-bit counter |

Note: The watchdog timer counter (WTCNT) is more difficult to write to than other registers to prevent from the erroneous writing to the register. Refer to section 11.2.3 Notes on Register Access.

### 11.2.2 Watchdog Timer Control/Status Register (WTCSR)

The watchdog timer control/status register (WTCSR) is an 8-bit read/write register composed of bits to select the clock used for the count, bits to select the timer mode, and overflow flags. The WTCSR is initialized to H'00 only by a power-on reset through the  $\overline{\text{RESET}}$  pin. When a WDT overflow causes an internal reset, the WTCSR retains its value. When used to count the clock settling time for canceling a software standby, it retains its value after counter overflow. Use a word access to write to the WTCSR, with H'A5 in the upper byte. Use a byte access to read WTCSR.

| Bit | Bit Name                   | Initial Value | R/W | Description                                                                                                                                                                                                                                                                                                     |

| 101: 1/256           | 4.36 ms                               |               |     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                      |                                       |        |       |          |       |           |        |           |        |           |         |            |         |             |          |             |          |
| 110: 1/1024          | 17.48 ms                              |               |     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                      |                                       |        |       |          |       |           |        |           |        |           |         |            |         |             |          |             |          |
| 111: 1/4096          | 69.91 ms                              |               |     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                      |                                       |        |       |          |       |           |        |           |        |           |         |            |         |             |          |             |          |

Note: The watchdog timer control/status register (WTCSR) is more difficult to write to than other registers to prevent from the erroneous writing to the register. Refer to section 11.2.3, Notes on Register Access.

### 11.2.3 Notes on Register Access

The WTCNT and WTCSR are more difficult to write to than other registers. The procedure for writing to these registers are given below.

**Writing to WTCNT and WTCSR:** These registers must be written by a word transfer instruction. They cannot be written by a byte or longword transfer instruction. When writing to WTCNT, set the upper byte to H'5A and transfer the lower byte as the write data, as shown in figure 11.2. When writing to WTCSR, set the upper byte to H'A5 and transfer the lower byte as the write data. This transfer procedure writes the lower byte data to WTCNT or WTCSR.

Figure 11.2 Writing to WTCNT and WTCSR

## 11.3 Operation

### 11.3.1 Canceling Software Standbys

The WDT can be used to cancel software standby mode with an NMI or other interrupts. The procedure is described below. (The WDT does not run when resets are used for canceling, so keep the RESETP pin or RESETM pin low until the clock stabilizes.)

1. Before transitioning to software standby mode, always clear the TME bit in WTCSR to 0. When the TME bit is 1, an erroneous reset or interval timer interrupt may be generated when the count overflows.
2. Set the type of count clock used in the CKS2 to CKS0 bits in WTCSR and the initial values for the counter in the WTCNT counter. These values should ensure that the time till count overflow is longer than the clock oscillation settling time.
3. Move to software standby mode by executing a SLEEP instruction to stop the clock.
4. The WDT starts counting by detecting the edge change of the NMI signal or detecting interrupts.
5. When the WDT count overflows, the CPG starts supplying the clock and the processor resumes operation. The WOVF flag in WTCSR is not set when this happens.
6. Since the WDT continues counting from H'00, set the STBY bit in the STBCR register to 0 in the interrupt processing program and this will stop the WDT. When the STBY bit remains 1, the SH7706 again enters the standby mode when the WDT has counted up to H'80. This standby mode can be canceled by power-on resets.

### 11.3.2 Changing the Frequency

To change the frequency used by the PLL, use the WDT. When changing the frequency only by switching the divider, do not use the WDT.

1. Before changing the frequency, always clear the TME bit in WTCSR to 0. When the TME bit is 1, an erroneous reset or interval timer interrupt may be generated when the count overflows.
2. Set the type of count clock used in the CKS2 to CKS0 bits of WTCSR and the initial values for the counter in the WTCNT counter. These values should ensure that the time till count overflow is longer than the clock oscillation settling time.
3. When the frequency control register (FRQCR) is written, the clock stops and the processor enters standby mode temporarily. The WDT starts counting.
4. When the WDT count overflows, the CPG resumes supplying the clock and the processor resumes operation. The WOVF flag in WTCSR is not set when this happens.
5. The counter stops at the values H'00 to H'01. The stop value depends on the clock ratio.
6. Confirm that the value of WTCNT is H'00 before writing WTCNT, when WTCNT is written after the frequency change.

### 11.3.3 Using Watchdog Timer Mode

1. Set the  $\overline{WT/IT}$  bit in the WTCSR register to 1, set the reset type in the RSTS bit, set the type of count clock in the CKS2 to CKS0 bits, and set the initial value of the counter in the WTCNT counter.
2. Set the TME bit in WTCSR to 1 to start the count in watchdog timer mode.
3. While operating in watchdog timer mode, rewrite the counter periodically to H'00 to prevent the counter from overflowing.
4. When the counter overflows, the WDT sets the WOVF flag in WTCSR to 1 and generates the type of reset specified by the RSTS bit. The counter then resumes counting.

When a reset occurs, and a high level is output from the STATUS0 and STATUS1 pins. The signal output period is about one cycle of the count clock for power-on reset, and about five cycles of the peripheral clock for manual reset.

### 11.3.4 Using Interval Timer Mode

When operating in interval timer mode, interval timer interrupts are generated at every overflow of the counter. This enables interrupts to be generated at set periods.

1. Clear the  $\overline{WT/IT}$  bit in the WTCSR register to 0, set the type of count clock in the CKS2 to CKS0 bits, and set the initial value of the counter in the WTCNT counter.
2. Set the TME bit in WTCSR to 1 to start the count in interval timer mode.
3. When the counter overflows, the WDT sets the IOVF flag in WTCSR to 1 and an interval timer interrupt request is sent to INTC. The counter then resumes counting.

## Section 12 Timer Unit(TMU)

This LSI uses a three-channel (channel 0 to 2) 32-bit timer unit (TMU).

Figure 12.1 shows a block diagram of the TMU.

### 12.1 Feature

The TMU has the following features:

- Each channel is provided with an auto-reload 32-bit down counter
- Channel 2 is provided with an input capture function
- All channels are provided with 32-bit constant registers and 32-bit down counters that can be read or written to at any time
- All channels generate interrupt requests when the 32-bit down counter underflows (H'00000000 → H'FFFFFFF)
- Allows selection between 6 counter input clocks: External clock (TCLK), on-chip RTC output clock (16 kHz), P $\phi$ /4, P $\phi$ /16, P $\phi$ /64, P $\phi$ /256. (P $\phi$  is the internal clock for peripheral modules.) See section 10, Clock Pulse Generator (CPG), for more information.
- All channels can operate when this LSI is in software standby mode: When the RTC output clock is being used as the counter input clock, this LSI is still able to count in software standby mode.
- Synchronized read: TCNT is a sequentially changing 32-bit register. Since the peripheral module used has an internal bus width of 16 bits, a time lag can occur between the time when the upper 16 bits and lower 16 bits are read. To correct the discrepancy in the counter read value caused by this time lag, a synchronization circuit is built into the TCNT so that the entire 32-bit data in the TCNT can be read at once.
- The maximum operating frequency of the 32-bit counter is 2 MHz on all channels: Operate the SH7706 so that the clock input to the timer counters of each channel (obtained by dividing the external clock and internal clock with the prescaler) does not exceed the maximum operating frequency.

**Figure 12.1 TMU Block Diagram**

## 12.2 Input/Output Pin

Table 12.1 shows the pin configuration of the TMU.

**Table 12.1 Pin Configuration**

| Channel                  | Pin  | I/O | Description                                                                              |
|--------------------------|------|-----|------------------------------------------------------------------------------------------|
| Clock input/clock output | TCLK | I/O | External clock input pin/input capture control input pin/realtime clock (RTC) output pin |

## 12.3 Register Description

The TMU has the following registers. Refer to section 23, List of Registers, for more details of the addresses and access sizes.

- Timer output control register (TOCR)
- Timer start register (TSTR)
- Timer constant register 0 (TCOR\_0)
- Timer counter 0 (TCNT\_0)
- Timer control register 0 (TCR\_0)
- Timer constant register 1 (TCOR\_1)
- Timer counter 1 (TCNT\_1)
- Timer control register 1 (TCR\_1)
- Timer constant register 2 (TCOR\_2)
- Timer counter 2 (TCNT\_2)
- Timer control register 2 (TCR\_2)
- Input capture register 2 (TCPR\_2)

### 12.3.1 Timer Output Control Register (TOCR)

TOCR is an 8-bit read/write register that selects whether to use the external TCLK pin as an external clock or an input capture control usage input pin, or an output pin for the on-chip RTC output clock. TOCR is initialized to H'00 by a power-on reset or manual reset, but is not initialized in standby mode.

### 12.3.2 Timer Start Register (TSTR)

TSTR is an 8-bit read/write register that selects whether to run or halt the timer counters (TCNT\_0 to TCNT\_2) for channels 0 to 2. TSTR is initialized to H'00 by a power-on reset or manual reset, but is not initialized in standby mode when the input clock selected for the channel is the on-chip RTC clock (RTCCLK). It is initialized in standby mode, changing the multiplying ratio of PLL circuit 1 or MSTP2 bit in STBCR is set to a logic one only when an external clock (TCLK) or the peripheral clock (Pφ) is used as the input clock.

### 12.3.3 Timer Control Register 0 to 2 (TCR\_0 to TCR\_2)

The timer control registers (TCR\_0 to TCR\_2) control the timer counters (TCNT\_0 to TCNT\_2) and interrupts. The TMU has three TCR\_0 to TCR\_2 registers for each channel.

The TCR\_0 to TCR\_2R registers are 16-bit read/write registers that control the issuance of interrupts when the flag indicating timer counter (TCNT\_0 to TCNT\_2) underflow has been set to 1, and also carry out counter clock selection. When the external clock has been selected, they also select its edge. Additionally, TCR\_2 controls the channel 2 input capture function and the issuance of interrupts during input capture. The TCR\_0 to TCR\_2 are initialized to H'0000 by a power-on reset and manual reset. They are not initialized in standby mode.

#### In cases of Channel 0 and 1:

### 12.3.4 Timer Constant Register 0 to 2 (TCOR\_0 to TCOR\_2)

TCOR\_0 to TCOR\_2 are specified the setting value for TCNT\_0 to TCNT\_2 when TCNT\_0 to TCNT\_2 are underflowed. TMU has 3 timer constant registers, one for each channel.

TCOR\_0 to TCOR\_2 is a 32-bit read/write register. TCOR is initialized to H'FFFFFFF by a power-on reset or manual reset; it is not initialized in standby mode, and retains its contents.

### 12.3.5 Timer Counters 0 to 2 (TCNT\_0 to TCNT\_2)

TCNT counts down according to the input of a clock. The timer counters are 32-bit read/write registers. The TMU has three timer counters, one for each channel. The clock input is selected using the TPSC2 to TPSC0 bits in the TCR\_0 to TCR\_2.

When a TCNT count-down results in an underflow (H'00000000 → H'FFFFFFFF), the underflow flag (UNF) in the timer control register (TCR) of the relevant channel is set. The TCOR value is simultaneously set in TCNT itself and the count-down continues from that value.

Because the internal bus for this LSI on-chip supporting modules is 16 bits wide, a time lag can occur between the time when the upper 16 bits and lower 16 bits are read. Since TCNT counts sequentially, this time lag can create discrepancies between the data in the upper and lower halves. To correct the discrepancy, a buffer register is connected to TCNT so that upper and lower halves are not read separately. The entire 32-bit data in TCNT can thus be read at once.

TCNT is initialized to H'FFFFFFFF by a power-on reset or manual reset; it is not initialized in standby mode, and retains its contents.

### 12.3.6 Input Capture Register 2(TCPR\_2)

The input capture register (TCPR\_2) is a read-only 32-bit register built only into timer 2. Control of TCPR\_2 setting conditions due to the TCLK pin is affected by the input capture function bits (ICPE1/ICPE2 and CKEG1/CKEG0) in TCR2. When a TCPR\_2 setting indication due to the TCLK pin occurs, the value of TCNT\_2 is copied into TCPR\_2.

TCNT\_2 is not initialized by a power-on reset or manual reset, or in standby mode.

## 12.4 Operation

Each of three channels has a 32-bit timer counter (TCNT\_0 to TCNT\_2) and a 32-bit timer constant register (TCOR\_0 to TCOR\_2). The TCNT counts down. The auto-reload function enables synchronized counting and counting by external events. Channel 2 has an input capture function.

### 12.4.1 Counter Operation

When the STR0 to STR2 bits in TSTR are set to 1, the corresponding timer counter (TCNT) starts counting. When a TCNT underflows, the UNF flag of the corresponding timer control register (TCR) is set. At this time, if the UNIE bit in TCR is 1, an interrupt request is sent to the CPU. Also at this time, the value is copied from TCOR to TCNT and the down-count operation is continued.

- **An example of the count operation setting flow**

The count operation is shown in figure 12.2.

**Figure 12.2 Setting the Count Operation**

- **Auto-Reload Count Operation:** Figure 12.3 shows the TCNT auto-reload operation.

**Figure 12.3 Auto-Reload Count Operation**

- **TCNT Count Timing:**

1. Internal Clock Operation: Set the TPSC2 to TPSC0 bits in TCR to select whether peripheral module clock  $P\phi$  or one of the four internal clocks created by dividing it is used ( $P\phi/4$ ,  $P\phi/16$ ,  $P\phi/64$ ,  $P\phi/256$ ). Figure 12.4 shows the timing.

**Figure 12.4 Count Timing when Internal Clock Is Operating**

2. **External Clock Operation:** Set the TPSC2 to TPSC0 bits in TCR to select the external clock (TCLK) as the timer clock. Use the CKEG1 and CKEG0 bits in TCR to select the detection edge. Rise, fall or both may be selected. The pulse width of the external clock must be at least 1.5 peripheral module clock cycles for single edges or 2.5 peripheral module clock cycles for both edges. A shorter pulse width will result in accurate operation. Figure 12.5 shows the timing for both-edge detection.

**Figure 12.5 Count Timing when External Clock is Operating (Both Edges Detected)**

3. **On-Chip RTC Clock Operation:** Set the TPSC2 to TPSC0 bits in TCR to select the on-chip RTC clock as the timer clock. Figure 12.6 shows the timing.

**Figure 12.6 Count Timing when On-Chip RTC Clock Is Operating**

## 12.4.2 Input Capture Function

Channel 2 has an input capture function (figure 12.7). When using the input capture function, set the TCLK pin to input mode with the TCOE bit in the timer output control register (TOCR) and set the timer operation clock to internal clock or on-chip RTC clock with the TPCS2 to TPCS0 bits in the timer control register (TCR\_2). Also, designate use of the input capture function and whether to generate interrupts on using it with the IPCE1 and IPCE0 bits in TCR\_2, and designate the use of either the rising or falling edge of the TCLK pin to set the timer counter (TCNT\_2) value into the input capture register (TCPR\_2) with the CKEG1 and CKEG0 bits in TCR\_2.

The input capture function cannot be used in standby mode.

**Figure 12.7 Operation Timing when Using the Input Capture Function  
(Using TCLK Rising Edge)**

# 12.5 Interrupts

There are two sources of TMU interrupts: underflow interrupts (TUNI) and interrupts when using the input capture function (TICPI2).

## 12.5.1 Status Flag Set Timing

UNF is set to 1 when the TCNT underflows. Figure 12.8 shows the timing.

Figure 12.8 UNF Set Timing

## 12.5.2 Status Flag Clear Timing

The status flag can be cleared by writing 0 from the CPU. Figure 12.9 shows the timing.

Figure 12.9 Status Flag Clear Timing

### 12.5.3 Interrupt Sources and Priorities

The TMU produces underflow interrupts for each channel. When the interrupt request flag and interrupt enable bit are both set to 1, the interrupt is requested. Codes are set in the exception event register (INTEVT, INTEVT2) for these interrupts and interrupt processing occurs according to the codes.

The relative priorities of channels can be changed using the interrupt controller (see section 4, Exception Processing, and section 6, Interrupt Controller (INTC)). Table 12.2 lists TMU interrupt sources.

**Table 12.2 TMU Interrupt Sources**

| Channel | Interrupt Source | Description               | Priority                                                                          |
|---------|------------------|---------------------------|-----------------------------------------------------------------------------------|
| 0       | TUNI0            | Underflow interrupt 0     | High                                                                              |
| 1       | TUNI1            | Underflow interrupt 1     |  |
| 2       | TUNI2            | Underflow interrupt 2     |                                                                                   |
|         | TICPI2           | Input capture interrupt 2 | Low                                                                               |

## 12.6 Usage Note

### 12.6.1 Writing to Registers

Synchronization processing is not performed for timer counting during register writes. When writing to registers, always clear the appropriate start bits for the channel (STR2 to STR0) in the timer start register (TSTR) to halt timer counting.

### 12.6.2 Reading Registers

Synchronization processing is performed for timer counting during register reads. When timer counting and register read processing are performed simultaneously, the register value before TCNT counting down (with synchronization processing) is read.

## Section 13 Realtime Clock (RTC)

This LSI has a realtime clock (RTC) with its own 32.768-kHz crystal oscillator. A block diagram of the RTC is shown in figure 13.1.

### 13.1 Feature

The RTC has following features:

- Clock and calendar functions (BCD display): seconds, minutes, hours, date, day of the week, month, and year
- 1-Hz to 64-Hz timer (binary display)
- Start/stop function
- 30-second adjust function
- Alarm interrupt: frame comparison of seconds, minutes, hours, date, day of the week, and month can be used as conditions for the alarm interrupt
- Cyclic interrupts: the interrupt cycle may be 1/256 second, 1/64 second, 1/16 second, 1/4 second, 1/2 second, 1 second, or 2 seconds
- Carry interrupt: a carry interrupt indicates when a carry occurs during a counter read
- Automatic leap year correction

**Figure 13.1 RTC Block Diagram**

## 13.2 Input/Output Pin

Table 13.1 shows the RTC pin configuration.

**Table 13.1 RTC Pin Configuration**

| Pin                                | Abbreviation         | I/O | Description                                                                                              |
|------------------------------------|----------------------|-----|----------------------------------------------------------------------------------------------------------|
| RTC oscillator crystal pin         | EXTAL2               | I   | Connects crystal to RTC oscillator* <sup>2</sup>                                                         |
| RTC oscillator crystal pin         | XTAL2                | O   | Connects crystal to RTC oscillator* <sup>2</sup>                                                         |
| Clock input/clock output           | TCLK                 | I/O | External clock input pin/input capture control input pin/realtime clock (RTC) output pin (shared by TMU) |
| Dedicated power-supply pin for RTC | V <sub>CC</sub> -RTC | —   | Dedicated power-supply pin for RTC* <sup>1</sup>                                                         |
| Dedicated GND pin for RTC          | V <sub>SS</sub> -RTC | —   | Dedicated GND pin for RTC* <sup>1</sup>                                                                  |

Note: 1. Except for in hardware standby mode, even if only the RTC is used (software standby mode), power must be supplied to all power supply pins, including these RTC power supply pins. In hardware standby mode, it is possible to stop supplying power to the power supply pins except for the RTC power supply pins.  
2. Pull-up (Vcc) EXTAL2, and open (NC) XTAL2 when the RTC is not used.

## 13.3 Register Description

RTC has the registers listed below. Refer to section 23, List of Registers, for more detail of the address and access size.

- 64-Hz counter (R64CNT)
- Second counter (RSECCNT)
- Minute counter (RMINCNT)
- Hour counter (RHRCNT)
- Day of week counter (RWKCNT)
- Date counter (RDAYCNT)
- Month counter (RMONCNT)
- Year counter (RYRCNT)
- Second alarm register (RSECAR)
- Minute alarm register (RMINAR)
- Hour alarm register (RHRAR)
- Day of week alarm register (RWKAR)
- Date alarm register (RDAYAR)
- Month alarm register (RMONAR)
- RTC control register 1 (RCR1)
- RTC control register 2 (RCR2)

### 13.3.1 64-Hz Counter (R64CNT)

The 64-Hz counter (R64CNT) is an 8-bit read-only register that indicates the state of the RTC divider circuit between 64 Hz and 1 Hz.

R64CNT is reset to H'00 by setting the RESET bit in RCR2 or the ADJ bit in RCR2 to 1.

R64CNT is not initialized by a power-on reset or manual reset, or in standby mode.

| Bit    | Bit Name  | Initial Value | R/W | Description                                                                                                                                                                                                                                                                                                                                                                                                |     |           |    |     |    |     |    |     |    |     |    |      |    |      |    |      |

### 13.3.2 Second Counter (RSECCNT)

The second counter (RSECCNT) is an 8-bit read/write register used for setting/counting in the BCD-coded second section of the RTC. The count operation is performed by a carry for each second of the 64-Hz counter.

The range of second can be set is 00 to 59 (decimal). Errant operation will result if any other value is set. Carry out write processing after halting the count operation with the START bit in RCR2.

RSECCNT is not initialized by a power-on reset or manual reset, or in standby mode.

| Bit    | Bit Name | Initial Value | R/W | Description                                                                                |
|--------|----------|---------------|-----|--------------------------------------------------------------------------------------------|
| 7      | —        | 0             | R   | Always read as 0.                                                                          |
| 6 to 4 | —        | —             | R/W | Counter for 10-unit of second in the BCD-code. The range can be set from 0 to 5 (decimal). |
| 3 to 0 | —        | —             | R/W | Counter for 1-unit of second in the BCD-code. The range can be set from 0 to 9 (decimal).  |

### 13.3.3 Minute Counter (RMINCNT)

The minute counter (RMINCNT) is an 8-bit read/write register used for setting/counting in the BCD-coded minute section of the RTC. The count operation is performed by a carry for each minute of the second counter.

The range of minute can be set is 00 to 59 (decimal). Errant operation will result if any other value is set. Carry out write processing after halting the count operation with the START bit in RCR2.

RMINCNT is not initialized by a power-on reset or manual reset, or in standby mode.

| Bit    | Bit Name | Initial Value | R/W | Description                                                                                |
|--------|----------|---------------|-----|--------------------------------------------------------------------------------------------|
| 7      | —        | 0             | R   | Always read as 0.                                                                          |
| 6 to 4 | —        | —             | R/W | Counter for 10-unit of minute in the BCD-code. The range can be set from 0 to 5 (decimal). |
| 3 to 0 | —        | —             | R/W | Counter for 1-unit of minute in the BCD-code. The range can be set from 0 to 9 (decimal).  |

### 13.3.4 Hour Counter (RHRCNT)

The hour counter (RHRCNT) is an 8-bit read/write register used for setting/counting in the BCD-coded hour section of the RTC. The count operation is performed by a carry for each 1 hour of the minute counter.

The range of hour can be set is 00 to 23 (decimal). Errant operation will result if any other value is set. Carry out write processing after halting the count operation with the START bit in RCR2.

RHRCNT is not initialized by a power-on reset or manual reset, or in standby mode.

| Bit    | Bit Name | Initial Value | R/W | Description                                                                              |
|--------|----------|---------------|-----|------------------------------------------------------------------------------------------|
| 7, 6   | —        | 0             | R   | Always read as 0.                                                                        |
| 5, 4   | —        | —             | R/W | Counter for 10-unit of hour in the BCD-code. The range can be set from 0 to 2 (decimal). |
| 3 to 0 | —        | —             | R/W | Counter for 1-unit of hour in the BCD-code. The range can be set from 0 to 9 (decimal).  |

### 13.3.5 Day of the Week Counter (RWKCNT)

The day of the week counter (RWKCNT) is an 8-bit read/write register used for setting/counting in the BCD-coded day of week section of the RTC. The count operation is performed by a carry for each day of the date counter.

The range for day of the week can be set is 0 to 6 (decimal). Errant operation will result if any other value is set. Carry out write processing after halting the count operation with the START bit in RCR2.

RWKCNT is not initialized by a power-on reset or manual reset, or in standby mode.

| Bit    | Bit Name | Initial Value | R/W  | Description                                                                                 |
|--------|----------|---------------|------|---------------------------------------------------------------------------------------------|
| 7 to 3 | —        | 0             | R    | Always read as 0.                                                                           |
| 2 to 0 | —        | —             | R/W  | Counter for the day of week in the BCD-code.<br>The range can be set from 0 to 6 (decimal). |
|        |          |               | Code | Day of Week                                                                                 |
|        |          |               | 0:   | Sunday                                                                                      |
|        |          |               | 1:   | Monday                                                                                      |
|        |          |               | 2:   | Tuesday                                                                                     |
|        |          |               | 3:   | Wednesday                                                                                   |
|        |          |               | 4:   | Thursday                                                                                    |
|        |          |               | 5:   | Friday                                                                                      |

### 13.3.6 Date Counter (RDAYCNT)

The date counter (RDAYCNT) is an 8-bit read/write register used for setting/counting in the BCD-coded date section of the RTC. The count operation is performed by a carry for each day of the hour counter.

The range of date can be set is 01 to 31 (decimal). Errant operation will result if any other value is set. Carry out write processing after halting the count operation with the START bit in RCR2.

RDAYCNT is not initialized by a power-on reset or manual reset, or in standby mode.

The RDAYCNT range that can be set changes with each month and in leap years. Please confirm the correct setting.

| Bit    | Bit Name | Initial Value | R/W | Description                                                                                 |
|--------|----------|---------------|-----|---------------------------------------------------------------------------------------------|
| 7, 6   | —        | 0             | R   | Always read as 0.                                                                           |
| 5, 4   | —        | —             | R/W | Counter for 10-unit of date in the BCD-code.<br>The range can be set from 0 to 3 (decimal). |
| 3 to 0 | —        | —             | R/W | Counter for 1-unit of date in the BCD-code.<br>The range can be set from 0 to 9 (decimal).  |

### 13.3.7 Month Counter (RMONCNT)

The month counter (RMONCNT) is an 8-bit read/write register used for setting/counting in the BCD-coded month section of the RTC. The count operation is performed by a carry for each month of the date counter.

The range of month can be set is 00 to 12 (decimal). Errant operation will result if any other value is set. Carry out write processing after halting the count operation with the START bit in RCR2.

RMONCNT is not initialized by a power-on reset or manual reset, or in standby mode.

| Bit    | Bit Name | Initial Value | R/W | Description                                                                                  |
|--------|----------|---------------|-----|----------------------------------------------------------------------------------------------|
| 7 to 5 | —        | 0             | R   | Always read as 0.                                                                            |
| 4      | —        | —             | R/W | Counter for 10-unit of month in the BCD-code.<br>The range can be set from 0 to 1 (decimal). |
| 3 to 0 | —        | —             | R/W | Counter for 1-unit of month in the BCD-code.<br>The range can be set from 0 to 9 (decimal).  |

### 13.3.8 Year Counter (RYRCNT)

The year counter (RYRCNT) is an 8-bit read/write register used for setting/counting in the BCD-coded year section of the RTC. The least significant 2 digits of the western calendar year are displayed. The count operation is performed by a carry for each year of the month counter.

The range for year can be set is 00 to 99 (decimal). Errant operation will result if any other value is set. Carry out write processing after halting the count operation with the START bit in RCR2 or using a carry flag.

RYRCNT is not initialized by a power-on reset or manual reset, or in standby mode.

Leap years are recognized by dividing the year counter value by 4 and obtaining a fractional result of 0.

| Bit    | Bit Name | Initial Value | R/W | Description                                                                                 |
|--------|----------|---------------|-----|---------------------------------------------------------------------------------------------|
| 7 to 4 | —        | —             | R/W | Counter for 10-unit of year in the BCD-code.<br>The range can be set from 0 to 9 (decimal). |
| 3 to 0 | —        | —             | R/W | Counter for 1-unit of year in the BCD-code.<br>The range can be set from 0 to 9 (decimal).  |

### 13.3.9 Second Alarm Register (RSECAR)

The second alarm register (RSECAR) is an 8-bit read/write register, and an alarm register corresponding to the BCD-coded second section counter RSECCNT of the RTC. When the ENB bit is set to 1, a comparison with the RSECCNT value is performed. From among the RSECAR/RMINAR/RHRAR/RWKAR/RDAYAR/RMONAR registers, the counter and alarm register comparison is performed only on those with ENB bits set to 1, and if each of those coincide, an RTC alarm interrupt is generated.

The range of second can be set is 00 to 59 (decimal). Errant operation will result if any other value is set.

The ENB bit in RSECAR is initialized to 0 by a power-on reset. The remaining RSECAR fields are not initialized by a power-on reset or manual reset, or in standby mode.

| Bit    | Bit Name | Initial Value | R/W | Description                                                                                               |
|--------|----------|---------------|-----|-----------------------------------------------------------------------------------------------------------|
| 7      | —        | 0             | R   | Second Alarm Enable<br>0: No compared<br>1: Compared                                                      |
| 6 to 4 | —        | —             | R/W | Setting value for 10-unit of second alarm in the BCD-code.<br>The range can be set from 0 to 5 (decimal). |
| 3 to 0 | —        | —             | R/W | Setting value for 1-unit of second alarm in the BCD-code.<br>The range can be set from 0 to 9 (decimal).  |

### 13.3.10 Minute Alarm Register (RMINAR)

The minute alarm register (RMINAR) is an 8-bit read/write register, and an alarm register corresponding to the BCD-coded minute section counter RMINCNT of the RTC. When the ENB bit is set to 1, a comparison with the RMINCNT value is performed. From among the RSECAR/RMINAR/RHRAR/RWKAR/RDAYAR/RMONAR registers, the counter and alarm register comparison is performed only on those with ENB bits set to 1, and if each of those coincide, an RTC alarm interrupt is generated.

The range of minute can be set is 00 to 59 (decimal). Errant operation will result if any other value is set.

The ENB bit in RMINAR is initialized by a power-on reset. The remaining RMINAR fields are not initialized by a power-on reset or manual reset, or in standby mode.

| Bit    | Bit Name | Initial Value | R/W | Description                                                                                               |
|--------|----------|---------------|-----|-----------------------------------------------------------------------------------------------------------|
| 7      | ENB      | 0             | R/W | Minute Alarm Enable<br>0: No compared<br>1: Compared                                                      |
| 6 to 4 | —        | —             | R/W | Setting value for 10-unit of minute alarm in the BCD-code.<br>The range can be set from 0 to 5 (decimal). |
| 3 to 0 | —        | —             | R/W | Setting value for 1-unit of minute alarm in the BCD-code.<br>The range can be set from 0 to 9 (decimal).  |

### 13.3.11 Hour Alarm Register (RHRAR)

The hour alarm register (RHRAR) is an 8-bit read/write register, and an alarm register corresponding to the BCD-coded hour section counter RHRCNT of the RTC. When the ENB bit is set to 1, a comparison with the RHRCNT value is performed. From among the RSECAR/RMINAR/RHRAR/RWKAR/RDAYAR/RMONAR registers, the counter and alarm register comparison is performed only on those with ENB bits set to 1, and if each of those coincide, an RTC alarm interrupt is generated.

The range of hour can be set is 00 to 23 (decimal). Errant operation will result if any other value is set.

The ENB bit in RHRAR is initialized by a power-on reset. The remaining RHRAR fields are not initialized by a power-on reset or manual reset, or in standby mode.

| Bit    | Bit Name | Initial Value | R/W | Description                                                                                             |
|--------|----------|---------------|-----|---------------------------------------------------------------------------------------------------------|
| 7      | ENB      | 0             | R/W | Hour Alarm Enable<br>0: No compared<br>1: Compared                                                      |
| 6      | —        | 0             | R   | Always read as 0.                                                                                       |
| 5, 4   | —        | —             | R/W | Setting value for 10-unit of hour alarm in the BCD-code.<br>The range can be set from 0 to 2 (decimal). |
| 3 to 0 | —        | —             | R/W | Setting value for 1-unit of hour alarm in the BCD-code.<br>The range can be set from 0 to 9 (decimal).  |

### 13.3.12 Day of the Week Alarm Register (RWKAR)

The day of the week alarm register (RWKAR) is an 8-bit read/write register, and an alarm register corresponding to the BCD-coded day of week section counter RWKCNT of the RTC. When the ENB bit is set to 1, a comparison with the RWKCNT value is performed. From among the RSECAR/RMINAR/RHRAR/RWKAR/RDAYAR/RMONAR registers, the counter and alarm register comparison is performed only on those with ENB bits set to 1, and if each of those coincide, an RTC alarm interrupt is generated.

The range of day of the week can be set 0 to 6 (decimal). Errant operation will result if any other value is set.

The ENB bit in RWKAR is initialized by a power-on reset. The remaining RWKAR fields are not initialized by a power-on reset or manual reset, or in standby mode.

| Bit    | Bit Name        | Initial Value | R/W | Description                                                                                                                                                                                                                                                                                                                                                                                                                           |      |                 |    |        |    |        |    |         |    |           |    |          |    |        |    |          |
|--------|-----------------|---------------|-----|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-----------------|----|--------|----|--------|----|---------|----|-----------|----|----------|----|--------|----|----------|
| 7      | ENB             | 0             | R/W | Day of the week Alarm Enable<br>0: No compared<br>1: Compared                                                                                                                                                                                                                                                                                                                                                                         |      |                 |    |        |    |        |    |         |    |           |    |          |    |        |    |          |

### 13.3.13 Date Alarm Register (RDAYAR)

The date alarm register (RDAYAR) is an 8-bit read/write register, and an alarm register corresponding to the BCD-coded date section counter RDAYCNT of the RTC. When the ENB bit is set to 1, a comparison with the RDAYCNT value is performed. From among the registers RSECAR, RMINAR, RHRAR, RWKAR, RDAYAR, RMONAR, the counter and alarm register comparison is performed only on those with ENB bits set to 1, and if each of those coincide, an RTC alarm interrupt is generated.

The range of date can be set 01 to 31 (decimal). Errant operation will result if any other value is set. The RDAYCNT range that can be set changes with some months and in leap years. Please confirm the correct setting.

The ENB bit in RDAYAR is initialized by a power-on reset. The remaining RDAYAR fields are not initialized by a power-on reset or manual reset, or in standby mode.

| Bit    | Bit Name | Initial Value | R/W | Description                                                                                             |
|--------|----------|---------------|-----|---------------------------------------------------------------------------------------------------------|
| 7      | ENB      | 0             | R/W | Date Alarm Enable<br>0: No compared<br>1: Compared                                                      |
| 6      | —        | 0             | R   | Always read as 0.                                                                                       |
| 5, 4   | —        | —             | R/W | Setting value for 10-unit of date alarm in the BCD-code.<br>The range can be set from 0 to 3 (decimal). |
| 3 to 0 | —        | —             | R/W | Setting value for 1-unit of date alarm in the BCD-code.<br>The range can be set from 0 to 9 (decimal).  |

### 13.3.14 Month Alarm Register (RMONAR)

The month alarm register (RMONAR) is an 8-bit read/write register, and an alarm register corresponding to the BCD-coded month section counter RMONCNT of the RTC. When the ENB bit is set to 1, a comparison with the RMONCNT value is performed. From among the registers RSECAR, RMINAR, RHRAR, RWKAR, RDAYAR, RMONAR, the counter and alarm register comparison is performed only on those with ENB bits set to 1, and if each of those coincide, an RTC alarm interrupt is generated.

The range of month can be set 01 to 12 (decimal). Errant operation will result if any other value is set.

The ENB bit in RMONAR is initialized by a power-on reset. The remaining RMONAR fields are not initialized by a power-on reset or manual reset, or in standby mode.

| Bit    | Bit Name | Initial Value | R/W | Description                                                                                              |
|--------|----------|---------------|-----|----------------------------------------------------------------------------------------------------------|
| 7      | ENB      | 0             | R/W | Month Alarm Enable<br>0: No compared<br>1: Compared                                                      |

| 3 to 0 | —        | —             | R/W | Setting value for 1-unit of month alarm in the BCD-code.<br>The range can be set from 0 to 9 (decimal).  |

### 13.3.15 RTC Control Register 1 (RCR1)

The RTC control register 1 (RCR1) is an 8-bit read/write register that affects carry flags and alarm flags. It also selects whether to generate interrupts for each flag. Because flags are sometimes set after an operand read, do not use this register in read-modify-write processing.

RCR1 is initialized to H'00 by a power-on reset. In a manual reset, all bits are initialized to 0 except for the CF flag, which is undefined. When using the CF flag, it must be initialized beforehand. This register is not initialized in standby mode.

| Bit | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                                                                                                                                                                                                                    |

### 13.3.16 RTC Control Register 2 (RCR2)

The RTC control register 2 (RCR2) is an 8-bit read/write register for periodic interrupt control, 30-second adjustment ADJ, divider circuit RESET, and RTC count start/stop control. It is initialized to H'09 by a power-on reset. It is initialized except for RTCEN and START by a manual reset. It is not initialized in standby mode, and retains its contents.

| Bit | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                                                                                                                                                                                                                          |

## 13.4 RTC Operation

### 13.4.1 Initial Settings of Registers after Power-On

All the registers should be set after the power is turned on.

### 13.4.2 Setting the Time

Figure 13.2 shows how to set the time when the clock is stopped. This works when the entire calendar or clock is to be set.

It is easy to set the time using a software program.

**Figure 13.2 Setting the Time**

### 13.4.3 Reading the Time

Figure 13.3 shows how to read the time. If a carry occurs while reading the time, the correct time will not be obtained, so it must be read again. Part (a) in figure 13.3 shows the method of reading the time without using interrupts; part (b) in figure 13.3 shows the method using carry interrupts. To keep programming simple, method (a) should normally be used.

**Figure 13.3 Reading the Time**

### 13.4.4 Alarm Function

Figure 13.4 shows how to use the alarm function.

Alarms can be generated using seconds, minutes, hours, day of the week, date, month, or any combination of these. Set the ENB bit (bit 7) in the register on which the alarm is placed to 1, and then set the alarm time in the lower bits. Clear the ENB bit in the register on which the alarm is placed to 0.

When the clock and alarm times match, 1 is set in the AF bit (bit 0) in RCR1. Alarm detection can be checked by reading this bit, but normally it is done by interrupt. If 1 is placed in the AIE bit (bit 3) in RCR1, an interrupt is generated when an alarm occurs.

**Figure 13.4 Using the Alarm Function**

### 13.4.5 Crystal Oscillator Circuit

Crystal oscillator circuit constants (recommended values) are shown in table 13.2, and the RTC crystal oscillator circuit in figure 13.5.

**Table 13.2 Recommended Oscillator Circuit Constants (Recommended Values)**

| fosc       | Cin         | Cout        |
|------------|-------------|-------------|
| 32.768 kHz | 10 to 22 pF | 10 to 22 pF |

- Notes:
1. Select either the  $C_{in}$  or  $C_{out}$  side for frequency adjustment variable capacitor according to requirements such as frequency range, degree of stability, etc.
  2. Built-in resistance value  $R_f$  (Typ value) = 10 M $\Omega$ ,  $R_D$  (Typ value) = 400 k $\Omega$
  3.  $C_{in}$  and  $C_{out}$  values include floating capacitance due to the wiring. Take care when using a ground plane.
  4. The crystal oscillation settling time depends on the mounted circuit constants, floating capacitance, etc., and should be decided after consultation with the crystal resonator manufacturer.
  5. Place the crystal resonator and load capacitors  $C_{in}$  and  $C_{out}$  as close as possible to the chip. (Correct oscillation may not be possible if there is externally induced noise in the EXTAL2 and XTAL2 pins.)
  6. Ensure that the crystal resonator connection pin (EXTAL2, XTAL2) wiring is routed as far away as possible from other power lines (except GND) and signal lines.

**Figure 13.5 Example of Crystal Oscillator Circuit Connection**

## 13.5 Usage Note

### 13.5.1 Register Writing during RTC Count

The following RTC registers cannot be written to during an RTC count (while bit 0 = 1 in RCR2).

RSECCNT, RMINCNT, RHRCNT, RDAYCNT, RWKCNT, RMONCNT, RYRCNT

The RTC count must be halted before writing to any of the above registers.

### 13.5.2 Use of Realtime Clock (RTC) Periodic Interrupts

The method of using the periodic interrupt function is shown in figure 13.6.

A periodic interrupt can be generated periodically at the interval set by the periodic interrupt enable flag (PES0 to PES2) in RCR2. When the time set by the PES0 to PES2 has elapsed, the PEF is set to 1.

The PEF is cleared to 0 upon periodic interrupt generation when the periodic interrupt enable flag (PES0 to PES2) is set. Periodic interrupt generation can be confirmed by reading this bit, but normally the interrupt function is used.

**Figure 13.6 Using Periodic Interrupt Function**

### 13.5.3 Timing for Setting ADJ Bit in RCR2

After the ADJ bit in RCR2 of the RTC is set to 1, it takes a maximum of approximately 91.6  $\mu$ s (when a 32.768-kHz crystal resonator is connected to the EXTAL2 pin) for the setting to affect the value read from the second counter (RSECCNT).

If the result of 30-second adjustment by the ADJ bit in RCR2 needs to be reflected in the value read from the second counter, be sure to read from the second counter only after at least 91.6  $\mu$ s (approximately) has passed after the ADJ bit has been set to 1.

Note that 30-second adjustment is actually performed for the second counter at the time the ADJ bit is set to 1, so this delay does not affect the RTC operation itself.

# Section 14 Serial Communication Interface (SCI)

This LSI has an on-chip serial communication interface (SCI) that supports both asynchronous and clock synchronous serial communication. It also has a multiprocessor communication function for serial communication among two or more processors. A block diagram of SCI is shown in figure 14.1, and the I/O ports are shown in figures 14.2 to 14.4.

## 14.1 Feature

- **Selectable from asynchronous or clock synchronous as the serial communications mode.**
- **Asynchronous mode:**
  - Serial data communications are synched by start-stop in character units. The SCI can communicate with a universal asynchronous receiver/transmitter (UART), an asynchronous communication interface adapter (ACIA), or any other communications chip that employs a standard asynchronous serial system. It can also communicate with two or more other processors using the multiprocessor communication function. There are 12 selectable serial data communication formats.
  - Data length: Seven or eight bits
  - Stop bit length: One or two bits
  - Parity: Even, odd, or none
  - Multiprocessor bit: 1 or 0
  - Receive error detection: Parity, overrun, and framing errors
  - Break detection: By reading the RxD0 pin level directly from the port Serial communication port data register (SCPDR) when a framing error occurs
- **Clock synchronous mode:**
  - Serial data communication is synchronized with a clock signal. The SCI can communicate with other chips having a clock synchronous communication function. One serial data communication format is available.
  - Data length: Eight bits
  - Receive error detection: Overrun errors
- **Full duplex communication**

The transmitting and receiving sections are independent, so the SCI can transmit and receive simultaneously. Both sections use double buffering, so continuous data transfer is possible in both the transmit and receive directions.
- **On-chip baud rate generator with selectable bit rates**
- **Internal or external transmit/receive clock source**

From either baud rate generator (internal) or SCK0 pin (external)

- **Four types of interrupts**

Transmit-data-empty, transmit-end, receive-data-full, and receive-error interrupts are requested independently.

- **Saving power**

When the SCI is not in use, it can be stopped by halting the clock supply for the saving power.

Figure 14.1 shows a SCI block diagram.

**Figure 14.1 SCI Block Diagram**

Legend

PDRW: SCPDR write

PDRR: SCPDR read

PCRW: SCPDR write

Note: \* When reading the SCK0 pin, clear the C/ $\bar{A}$  bit in SCSMR and the CKE1 and CKE0 bits in SCSCR to 0, and set the SCP1MD1 bit in SCPDR to 1.

**Figure 14.2 SCPT[1]/SCK0 Pin**

**Figure 14.3 SCPT[0]/TxD0 Pin**

**Figure 14.4 SCPT[0]/Rx0 Pin**

## 14.2 Input/Output Pin

The SCI has the serial pins summarized in table 14.1.

**Table 14.1 SCI Pins**

| Pin Name          | Abbreviation | I/O    | Function             |
|-------------------|--------------|--------|----------------------|
| Serial clock pin  | SCK0         | I/O    | Clock I/O            |
| Receive data pin  | RxD0         | Input  | Receive data input   |
| Transmit data pin | TxD0         | Output | Transmit data output |

Note: They are made to function as serial pins by performing SCI operation settings with the TE, RE, CKEI, and CKEO bits in SCSCR and the C/ $\bar{A}$  bit in SCSMR. Break state transmission and detection can be performed by means of the SCI's SCPDR.

## 14.3 Register Description

The SCI has the registers listed below. These registers select the communication mode (asynchronous or clock synchronous), specify the data format and bit rate, and control the transmitter and receiver sections.

SCI has the registers listed below. Refer to section 23, List of Registers, for more details of the addresses and access sizes.

- Serial mode register (SCSMR)
- Bit rate register (SCBRR)
- Serial control register (SCSCR)
- Transmit data register (SCTDR)
- Serial status register (SCSSR)
- Receive data register (SCRDR)
- SC port control register (SCPCR)
- SC port data register (SCPDR)

### 14.3.1 Receive Shift Register (SCRSR)

The receive shift register (SCRSR) is an 8-bit register that receives serial data. Data input at the RxD pin is loaded into the SCRSR in the order received, LSB (bit 0) first, converting the data to parallel form. When one byte has been received, it is automatically transferred to the SCRDR. The CPU cannot read or write the SCRSR directly.

### 14.3.2 Receive Data Register (SCRDR)

The receive data register (SCRDR) is an 8-bit register that stores serial receive data. The SCI completes the reception of one byte of serial data by moving the received data from the SCRSR into the SCRDR for storage. The SCRSR is then ready to receive the next data. This double buffering allows the SCI to receive data continuously.

The CPU can read but not write the SCRDR. The SCRDR is initialized to H'00 by a reset or in standby or module standby modes.

### 14.3.3 Transmit Shift Register (SCTSR)

The transmit shift register (SCTSR) transmits serial data. The SCI loads transmit data from the SCTDR into the SCTSR, then transmits the data serially to the TxD0 pin, LSB (bit 0) first. After transmitting one-byte data, the SCI automatically loads the next transmit data from the SCTDR into the SCTSR and starts transmitting again. If the TDRE bit of the SCSSR is 1, however, the SCI does not load the SCTDR contents into the SCTSR. The CPU cannot read or write the SCTSR directly.

### 14.3.4 Transmit Data Register (SCTDR)

The transmit data register (SCTDR) is an eight-bit register that stores data for serial transmission. When the SCI detects that the SCTSR is empty, it moves transmit data written in the SCTDR into the SCTSR and starts serial transmission. Continuous serial transmission is possible by writing the next transmit data in the SCTDR during serial transmission from the SCTSR.

The CPU can always read and write the SCTDR. The SCTDR is initialized to H'FF by a reset or in standby and module standby modes.

### 14.3.5 Serial Mode Register (SCSMR)

The serial mode register (SCSMR) is an eight-bit register that specifies the SCI serial communication format and selects the clock source for the baud rate generator.

The CPU can always read and write the SCSMR.

| Bit | Bit Name          | Initial Value | R/W | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

### 14.3.6 Serial Control Register (SCSCR)

The serial control register (SCSCR) operates the SCI transmitter/receiver, selects the serial clock output in the asynchronous mode, enables/disables interrupt requests, and selects the transmit/receive clock source. The CPU can always read and write the SCSCR.

| Bit | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

### 14.3.7 Serial Status Register (SCSSR)

The serial status register (SCSSR) is an 8-bit register containing multiprocessor bit values, and status flags that indicate SCI operating state.

The CPU can always read and write the SCSSR, but cannot write 1 in the status flags (TDRE, RDRF, ORER, PER, and FER). These flags can be cleared to 0 only if they have first been read (after being set to 1). Bits 2 (TEND) and 1 (MPB) are read-only bits that cannot be written.

| Bit | Bit Name | Initial Value | R/W    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

Note: \* The only value that can be written is a 0 to clear the flag.

### 14.3.8 SC Port Control Register (SCPCR)

The SC port control register (SCPCR) controls the direction of I/O signals on the SCI and SCIF pins. SCPCR settings are used to perform I/O direction control, enabling data written in SCPDR to be output to the TxD0 pin, data read from the RxD0 pin to be input, and the breaking of serial transmission/reception. It is also possible to read data on and write output data to the SCK0 pin. The I/O controls on the SCI and SCIF pins are performed using bits 3 to 0, and bits 11 to 4 in SCPCR, respectively.

### 14.3.9 SC Port Data Register (SCPDR)

The SC port data register (SCPDR) controls data on the SCI and SCIF pins. The data controls on the SCI and SCIF pins are performed using bits 1 and 0, and bits 5 and 2 in SCPDR, respectively.

| Bit | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| 1   | SCP1DT   | 0             | R/W | Serial clock port data:<br>Specifies the serial port SCK0 pin I/O data. Input or output is specified by the SCP1MD0 and SCP1MD1 bits. In output mode, the value of the SCP1DT bit is output to the SCK0 pin.<br>0: I/O data is low (0).<br>1: I/O data is high (1).                                                                                                                                                                                                                                                                               |
| 0   | SCP0DT   | 0             | R/W | Serial port break data:<br>Specifies the serial port RxD0 pin input data and TxD0 pin output data. The TxD0 pin output condition is specified by the SCP0MD0 and SCP0MD1 bits. When the TxD0 pin is set to output mode, the value of the SCP0DT bit is output to the TxD0 pin. The RxD0 pin value is read from the SCP0DT bit regardless of the values of the SCP0MD0 and SCP0MD1 bits, if RE in the SCSCR is set to 1. The initial value of this bit after a power-on reset is undefined.<br>0: I/O data is low (0).<br>1: I/O data is high (1). |

### 14.3.10 Bit Rate Register (SCBRR)

The bit rate register (SCBRR) is an eight-bit register that, together with the baud rate generator clock source selected by the CKS1 and CKS0 bits in SCSMR, determines the serial transmit/receive bit rate.

The CPU can always read and write the SCBRR. The SCBRR is initialized to H'FF by a reset or in module standby or standby mode. Each channel has independent baud rate generator control, so different values can be set in two channels.

The SCBRR setting is calculated as follows:

$$\text{Asynchronous mode: } N = \left[ \frac{P\phi}{(64 \times 2^{2n-1} \times B)} \right] \times 10^6 - 1$$

$$\text{Clock synchronous mode: } N = \left[ \frac{P\phi}{(8 \times 2^{2n-1} \times B)} \right] \times 10^6 - 1$$

B: Bit rate (bit/s)

N: SCBRR setting for baud rate generator ( $0 \leq N \leq 255$ )

P $\phi$ : Operating frequency for peripheral modules (MHz)

n: Baud rate generator clock source ( $n = 0, 1, 2, 3$ ) (for the clock sources and values of n, see table 14.2.)

**Table 14.2 SCSMR Settings**

| n | Clock Source | SCSMR Settings |      |
|---|--------------|----------------|------|
|   |              | CKS1           | CKS0 |
| 0 | P $\phi$     | 0              | 0    |
| 1 | P $\phi$ /4  | 0              | 1    |
| 2 | P $\phi$ /16 | 1              | 0    |
| 3 | P $\phi$ /64 | 1              | 1    |

Note: Find the bit rate error for the asynchronous mode by the following formula:

$$\text{Error (\%)} = \left\{ \frac{P\phi \times 10^6}{(N + 1) \times B \times 64 \times 2^{2n-1}} - 1 \right\} \times 100$$

Table 14.3 lists examples of SCBRR settings in the asynchronous mode; table 14.4 lists examples of SCBRR settings in the clock synchronous mode.

**Table 14.3 Bit Rates and SCBRR Settings in Asynchronous Mode**

## 14.4 Operation

For serial communication, the SCI has an asynchronous mode in which characters are synchronized individually, and a clock synchronous mode in which communication is synchronized with clock pulses. Asynchronous/clock synchronous mode and the transmission format are selected in SCSMR, as listed in table 14.8. The SCI clock source is selected by the combination of the  $\overline{C/A}$  bit in SCSMR and the CKE1 and CKE0 bits in SCSCR, as listed in table 14.9.

### Asynchronous Mode:

- Data length is selectable: seven or eight bits.
- Parity and multiprocessor bits are selectable. So is the stop bit length (one or two bits). The combination of the preceding selections constitutes the communication format and character length.
- In receiving, it is possible to detect framing errors, parity errors, overrun errors and breaks.
- An internal or external clock can be selected as the SCI clock source.
  - When an internal clock is selected, the SCI operates on the clock of the on-chip baud rate generator, and can output a serial clock signal with a frequency matching the bit rate.
  - When an external clock is selected, the external clock input must have a frequency 16 times the bit rate. (The on-chip baud rate generator is not used.)

### Clock Synchronous Mode:

- The transmission/reception format has a fixed eight-bit data length.
- In receiving, it is possible to detect overrun errors.
- An internal or external clock can be selected as the SCI clock source.
  - When an internal clock is selected, the SCI operates on the clock of the on-chip baud rate generator, and outputs a synchronous clock signal to external devices.
  - When an external clock is selected, the SCI operates on the input synchronous clock. The on-chip baud rate generator is not used.

**Table 14.8 Serial Mode Register Settings and SCI Communication Formats**

| Mode                 | SCSMR Settings |              |             |             |               | SCI Communication Format |               |                                            |                    |        |        |   |       |         |     |       |

14.4.1    Operation in Asynchronous Mode

In the asynchronous mode, each transmitted or received character begins with a start bit and ends with a stop bit. Serial communication is synchronized one character at a time.

The transmitting and receiving sections of the SCI are independent, so full duplex communication is possible. The transmitter and receiver are both double buffered, so data can be written and read while transmitting and receiving are in progress, enabling continuous transmitting and receiving.

Figure 14.5 shows the general format of asynchronous serial communication. In asynchronous serial communication, the communication line is normally held in the mark (high) state. The SCI monitors the line and starts serial communication when the line goes to the space (low) state, indicating a start bit. One serial character consists of a start bit (low), data (LSB first), parity bit (high or low), and stop bit (high), in that order.

When receiving in the asynchronous mode, the SCI synchronizes on the falling edge of the start bit. The SCI samples each data bit on the eighth pulse of a clock with a frequency 16 times the bit rate. Receive data is latched at the center of each bit.

Figure 14.5    Data Format in Asynchronous Communication

**Transmit/Receive Formats:** Table 14.10 lists the 11 communication formats that can be selected in the asynchronous mode. The format is selected by settings in the SCSMR.

**Table 14.10 Serial Communication Formats (Asynchronous Mode)**

| SCSMR Bits |    |    |      | Serial Transmit/Receive Format and Frame Length |            |   |   |   |   |   |   |      |      |      |      |
|------------|----|----|------|-------------------------------------------------|------------|---|---|---|---|---|---|------|------|------|------|
| CHR        | PE | MP | STOP | 1                                               | 2          | 3 | 4 | 5 | 6 | 7 | 8 | 9    | 10   | 11   | 12   |
| 0          | 0  | 0  | 0    | START                                           | 8-Bit data |   |   |   |   |   |   |      | STOP |      |      |
| 0          | 0  | 0  | 1    | START                                           | 8-Bit data |   |   |   |   |   |   |      | STOP | STOP |      |
| 0          | 1  | 0  | 0    | START                                           | 8-Bit data |   |   |   |   |   |   |      | P    | STOP |      |
| 0          | 1  | 0  | 1    | START                                           | 8-Bit data |   |   |   |   |   |   |      | P    | STOP | STOP |
| 1          | 0  | 0  | 0    | START                                           | 7-Bit data |   |   |   |   |   |   | STOP |      |      |      |
| 1          | 0  | 0  | 1    | START                                           | 7-Bit data |   |   |   |   |   |   | STOP | STOP |      |      |
| 1          | 1  | 0  | 0    | START                                           | 7-Bit data |   |   |   |   |   |   | P    | STOP |      |      |
| 1          | 1  | 0  | 1    | START                                           | 7-Bit data |   |   |   |   |   |   | P    | STOP | STOP |      |
| 0          | —  | 1  | 0    | START                                           | 8-Bit data |   |   |   |   |   |   |      | MPB  | STOP |      |
| 0          | —  | 1  | 1    | START                                           | 8-Bit data |   |   |   |   |   |   |      | MPB  | STOP | STOP |
| 1          | —  | 1  | 0    | START                                           | 7-Bit data |   |   |   |   |   |   | MPB  | STOP |      |      |
| 1          | —  | 1  | 1    | START                                           | 7-Bit data |   |   |   |   |   |   | MPB  | STOP | STOP |      |

**Legend**

— : Don't care bits

START: Start bit

STOP: Stop bit

P: Parity bit

MPB: Multiprocessor bit

**Clock:** An internal clock generated by the on-chip baud rate generator or an external clock input from the SCK0 pin can be selected as the SCI transmit/receive clock. The clock source is selected by the  $C/\bar{A}$  bit in SCSMR and bits CKE1 and CKE0 in the SCSCR (table 14.9).

When an external clock is input on the SCK0 pin, it must have a frequency equal to 16 times the desired bit rate.

When the SCI operates on an internal clock, it can output a clock signal on the SCK0 pin. The frequency of this output clock is equal to the bit rate. The phase is aligned as in figure 14.6 so that the rising edge of the clock occurs at the center of each transmit data bit.

**Figure 14.6 Output Clock and Serial Data Timing (Asynchronous Mode)**

**Transmitting and Receiving Data (SCI Initialization (Asynchronous Mode)):** Before transmitting or receiving, clear the TE and RE bits to 0 in the serial control register (SCSCR), then initialize the SCI as follows.

When changing the operation mode or communication format, always clear the TE and RE bits to 0 before following the procedure given below. Clearing TE to 0 sets TDRE to 1 and initializes the transmit shift register (SCTSR). Clearing RE to 0, however, does not initialize the RDRF, PER, FER, and ORER flags or receive data register (SCRDR), which retain their previous contents.

When an external clock is used, the clock should not be stopped during initialization or subsequent operation. SCI operation becomes unreliable if the clock is stopped.

Figure 14.7 is a sample flowchart for initializing the SCI.

**Figure 14.7 Sample Flowchart for SCI Initialization**

**Transmitting Serial Data (Asynchronous Mode):** Figure 14.8 shows a sample flowchart for transmitting serial data. Serial data transmission should be carried out in the following procedure after setting the SCI in a transmission-enabled state.

**Figure 14.8 Sample Flowchart for Transmitting Serial Data**

In transmitting serial data, the SCI operates as follows:

1. The SCI monitors the TDRE bit in the SCSSR. When TDRE is cleared to 0, the SCI recognizes that the transmit data register (SCTDR) contains new data, and loads this data from the SCTDR into the SCTSR.
2. After loading the data from the SCTDR into the SCTSR, the SCI sets the TDRE bit to 1 and starts transmitting. If the transmit-data-empty interrupt enable bit (TIE) is set to 1 in the SCSCR, the SCI requests a transmit-data-empty interrupt (TXI) at this time. Serial transmit data is transmitted in the following order from the TxD0 pin:
  - a. Start bit: One 0 bit is output.
  - b. Transmit data: Seven or eight bits of data are output, LSB first.
  - c. Parity bit or multiprocessor bit: One parity bit (even or odd parity) or one multiprocessor bit is output. Formats in which neither a parity bit nor a multiprocessor bit is output can also be selected.
  - d. Stop bit: One or two 1 bits (stop bits) are output.
  - e. Marking: Output of 1 bits continues until the start bit of the next transmit data.
3. The SCI checks the TDRE bit when it outputs the stop bit. If TDRE is 0, the SCI loads new data from the SCTDR into the SCTSR, outputs the stop bit, then begins serial transmission of the next frame. If TDRE is 1, the SCI sets the TEND bit to 1 in the SCSSR, outputs the stop bit, then continues output of 1 bits (marking). If the transmit-end interrupt enable bit (TEIE) in the SCSCR is set to 1, a transmit-end interrupt (TEI) is requested.

Figure 14.9 shows an example of SCI transmit operation in the asynchronous mode.

**Figure 14.9 SCI Transmit Operation in Asynchronous Mode**

**Receiving Serial Data (Asynchronous Mode):** Figure 14.10 shows a sample flowchart for receiving serial data. Serial data reception should be carried out in the following procedure after setting the SCI in a reception-enabled state.

**Figure 14.10 Sample Flowchart for Receiving Serial Data**

**Figure 14.10 Sample Flowchart for Receiving Serial Data (cont)**

In receiving, the SCI operates as follows:

1. The SCI monitors the communication line. When it detects a start bit (0), the SCI synchronizes internally and starts receiving.
2. Receive data is stored into the SCRSR in order from the LSB to the MSB.
3. The parity bit and stop bit are received. After receiving these bits, the SCI makes the following checks:
  - a. Parity check: The number of 1s in the receive data must match the even or odd parity setting of the O/E bit in the SCSMR.
  - b. Stop bit check: The stop bit value must be 1. If there are two stop bits, only the first stop bit is checked.
  - c. Status check: RDRF must be 0 so that receive data can be loaded from the SCRSR into the SCRDR.

If these checks all pass, the SCI sets RDRF to 1 and stores the received data in the SCRDR. If one of the checks fails (receive error), the SCI operates as indicated in table 14.11.

Note: When a receive error flag is set, further receiving is disabled. The RDRF bit is not set to 1. Be sure to clear the error flags.

4. After setting RDRF to 1, if the receive-data-full interrupt enable bit (RIE) is set to 1 in the SCSCR, the SCI requests a receive-data-full interrupt (RXI). If one of the error flags (ORER, PER, or FER) is set to 1 and the receive-data-full interrupt enable bit (RIE) in the SCSCR is also set to 1, the SCI requests a receive-error interrupt (ERI).

**Table 14.11 Receive Error Conditions and SCI Operation**

| Receive Error  | Abbreviation | Condition                                                            | Data Transfer                                 |
|----------------|--------------|----------------------------------------------------------------------|-----------------------------------------------|
| Overflow error | ORER         | Receiving of next data ends while RDRF is still set to 1 in SCSSR    | Receive data not loaded from SCRSR into SCRDR |
| Framing error  | FER          | Stop bit is 0                                                        | Receive data loaded from SCRSR into SCRDR     |
| Parity error   | PER          | Parity of receive data differs from even/odd parity setting in SCSMR | Receive data loaded from SCRSR into SCRDR     |

Figure 14.11 shows an example of SCI receive operation in the asynchronous mode.

**Figure 14.11 SCI Receive Operation**

#### 14.4.2 Multiprocessor Communication

The multiprocessor communication function enables several processors to share a single serial communication line. The processors communicate in the asynchronous mode using a format with an additional multiprocessor bit (multiprocessor format).

In multiprocessor communication, each receiving processor is addressed by a unique ID. A serial communication cycle consists of an ID-sending cycle that identifies the receiving processor, and a data-sending cycle. The multiprocessor bit distinguishes ID-sending cycles from data-sending cycles. The transmitting processor starts by sending the ID of the receiving processor with which it wants to communicate as data with the multiprocessor bit set to 1. Next the transmitting processor sends transmit data with the multiprocessor bit cleared to 0.

Receiving processors skip incoming data until they receive data with the multiprocessor bit set to 1. When they receive data with the multiprocessor bit set to 1, receiving processors compare the data with their IDs. The receiving processor with a matching ID continues to receive further incoming data. Processors with IDs not matching the received data skip further incoming data until they again receive data with the multiprocessor bit set to 1. Multiple processors can send and receive data in this way.

Figure 14.12 shows an example of communication among processors using the multiprocessor format.

**Figure 14.12 Communication Among Processors Using Multiprocessor Format**

**Communication Formats:** Four formats are available. Parity-bit settings are ignored when the multiprocessor format is selected. For details see table 14.10.

**Clock:** See the description in the asynchronous mode section.

**Transmitting Multiprocessor Serial Data:** Figure 14.13 shows a sample flowchart for transmitting multiprocessor serial data. Transmission of multiprocessor serial data should be carried out in the following procedure after setting the SCI in a transmission-enabled state.

**Figure 14.13 Sample Flowchart for Transmitting Multiprocessor Serial Data**

In transmitting serial data, the SCI operates as follows:

1. The SCI monitors the TDRE bit in the SCSSR. When TDRE is cleared to 0 the SCI recognizes that the SCTDR contains new data, and loads this data from the SCTDR into the SCTSR.
2. After loading the data from the SCTDR into the SCTSR, the SCI sets the TDRE bit to 1 and starts transmitting. If the transmit-data-empty interrupt enable bit (TIE) in the SCSCR is set to 1, the SCI requests a transmit-data-empty interrupt (TXI) at this time. Serial transmit data is transmitted in the following order from the TxD0 pin:
  - A. Start bit: One 0 bit is output.
  - B. Transmit data: Seven or eight bits are output, LSB first.
  - C. Multiprocessor bit: One multiprocessor bit (MPBT value) is output.
  - D. Stop bit: One or two 1 bits (stop bits) are output.
  - E. Marking: Output of 1 bits continues until the start bit of the next transmit data.
3. The SCI checks the TDRE bit when it outputs the stop bit. If TDRE is 0, the SCI loads data from the SCTDR into the SCTSR, outputs the stop bit, then begins serial transmission of the next frame. If TDRE is 1, the SCI sets the TEND bit in the SCSSR to 1, outputs the stop bit, then continues output of 1 bits in the marking state. If the transmit-end interrupt enable bit (TEIE) in the SCSCR is set to 1, a transmit-end interrupt (TEI) is requested at this time.

Figure 14.14 shows SCI transmission in the multiprocessor format.

**Figure 14.14 SCI Multiprocessor Transmit Operation**

**Receiving Multiprocessor Serial Data:** Figure 14.15 shows a sample flowchart for receiving multiprocessor serial data. Reception of multiprocessor serial data should be carried out in the following procedure after setting the SCI in a reception-enabled state.

**Figure 14.15 Sample Flowchart for Receiving Multiprocessor Serial Data**

**Figure 14.15 Sample Flowchart for Receiving Multiprocessor Serial Data (cont)**

Figure 14.16 shows an example of SCI receive operation using a multiprocessor format.

(a) Own ID does not matches data

(b) Own ID matches data

### Figure 14.16 Example of SCI Receive Operation

### 14.4.3 Clock Synchronous Operation

In the clock synchronous mode, the SCI transmits and receives data in synchronization with clock pulses. This mode is suitable for high-speed serial communication.

The SCI transmitter and receiver are independent, so full-duplex communication is possible while sharing the same clock. The transmitter and receiver are also double buffered, so continuous transmitting or receiving is possible by reading or writing data while transmitting or receiving is in progress.

Figure 14.17 shows the general format in clock synchronous serial communication.

**Figure 14.17 Data Format in Clock Synchronous Communication**

In clock synchronous serial communication, each data bit is output on the communication line from one falling edge of the serial clock to the next. Data are guaranteed valid at the rising edge of the serial clock. In each character, the serial data bits are transmitted in order from the LSB (first) to the MSB (last). After output of the MSB, the communication line remains in the state of the MSB. In the clock synchronous mode, the SCI transmits or receives data by synchronizing with the rising edge of the serial clock.

**Communication Format:** The data length is fixed at eight bits. No parity bit or multiprocessor bit can be added.

**Clock:** An internal clock generated by the on-chip baud rate generator or an external clock input from the SCK0 pin can be selected as the SCI transmit/receive clock. The clock source is selected by the  $\overline{C/A}$  bit in SCSMR and bits CKE1 and CKE0 in the SCSCR. See table 14.9.

When the SCI operates on an internal clock, it outputs the clock signal at the SCK0 pin. Eight clock pulses are output per transmitted or received character. When the SCI is not transmitting or receiving, the clock signal remains in the high state. When only receiving, the SCI receives in 2-character units, so a 16 pulse synchronization clock is output. To receive in 1-character units, select an external clock source.

**Transmitting and Receiving Data (SCI Initialization (clock synchronous mode)):** Before transmitting, receiving, or changing the mode or communication format, the software must clear the TE and RE bits to 0 in SCSCR, then initialize the SCI. Clearing TE to 0 sets TDRE to 1 and initializes the SCTSR. Clearing RE to 0, however, does not initialize the RDRF, PER, FER, and ORER flags and SCRDR, which retain their previous contents.

Figure 14.18 is a sample flowchart for initializing the SCI.

**Figure 14.18 Sample Flowchart for SCI Initialization**

**Transmitting Serial Data (Clock Synchronous Mode):** Figure 14.19 shows a sample flowchart for transmitting serial data. Transmission of serial data should be carried out in the following procedure after setting the SCI in a transmission-enabled state.

**Figure 14.19 Sample Flowchart for Serial Transmitting**

In transmitting serial data, the SCI operates as follows:

1. The SCI monitors the TDRE bit in the SCSSR. When TDRE is cleared to 0 the SCI recognizes that the SCTDR contains new data and loads this data from the SCTDR into the SCTSR.
2. After loading the data from the SCTDR into the SCTSR, the SCI sets the TDRE bit to 1 and starts transmitting. If the transmit-data-empty interrupt enable bit (TIE) in the SCSCR is set to 1, the SCI requests a transmit-data-empty interrupt (TXI) at this time.  
If clock output mode is selected, the SCI outputs eight synchronous clock pulses. If an external clock source is selected, the SCI outputs data in synchronization with the input clock. Data are output from the TxD0 pin in order from the LSB (bit 0) to the MSB (bit 7).
3. The SCI checks the TDRE bit when it outputs the MSB (bit 7). If TDRE is 0, the SCI loads data from the SCTDR into the SCTSR, then begins serial transmission of the next frame. If TDRE is 1, the SCI sets the TEND bit in the SCSSR to 1, transmits the MSB, then holds the transmit data pin (TxD0) in the MSB state. If the TEIE in the SCSCR is set to 1, a transmit-end interrupt (TEI) is requested at this time.
4. After the end of serial transmission, the SCK0 pin is held in the high state.

Figure 14.20 shows an example of SCI transmit operation.

**Figure 14.20 Example of SCI Transmit Operation**

**Receiving Serial Data (Clock Synchronous Mode):** Figure 14.21 shows a sample flowchart for receiving serial data. Serial data reception should be carried out in the procedure described below after setting the SCI in a reception-enabled state. When switching from the asynchronous mode to the clock synchronous mode, make sure that ORER, PER, and FER are cleared to 0. If PER or FER is set to 1, the RDRF bit will not be set and both transmitting and receiving will be disabled.

**Figure 14.21 Sample Flowchart for Serial Data Receiving**

**Figure 14.21 Sample Flowchart for Serial Data Receiving (cont)**

In receiving, the SCI operates as follows:

1. The SCI synchronizes with serial clock input or output and initializes internally.
2. Receive data is stored into the SCRSR in order from the LSB to the MSB. After receiving the data, the SCI checks that RDRF is 0 so that receive data can be loaded from the SCRSR into the SCRDR. If this check is passed, the SCI sets RDRF to 1 and stores the received data in the SCRDR. If the check is not passed (receive error), the SCI operates as indicated in table 14.11. This state prevents further transmission or reception. While receiving, the RDRF bit is not set to 1. Be sure to clear the error flag.
3. After setting RDRF to 1, if the RIE is set to 1 in the SCSCR, the SCI requests a receive-data-full interrupt (RXI). If the ORER bit is set to 1 and the RIE in the SCSCR is also set to 1, the SCI requests a receive-error interrupt (ERI).

Figure 14.22 shows an example of the SCI receive operation.

**Figure 14.22 Example of SCI Receive Operation**

**Transmitting and Receiving Serial Data Simultaneously (Clock Synchronous Mode):** Figure 14.23 shows a sample flowchart for transmitting and receiving serial data simultaneously. Simultaneous transmission and reception of serial data should be carried out in the following procedure after setting the SCI in a transmission/reception-enabled state.

Note: In switching from transmitting or receiving to simultaneous transmitting and receiving, clear both TE and RE to 0, then set both TE and RE to 1.

**Figure 14.23 Sample Flowchart for Serial Data Transmitting/Receiving**

## 14.5 SCI Interrupt Sources

The SCI has four interrupt sources in each channel: Transmit-end (TEI), receive-error (ERI), receive-data-full (RXI), and transmit-data-empty (TXI). Table 14.12 lists the interrupt sources and indicates their priority. These interrupts can be enabled and disabled by the TIE, RIE, and TEIE bits in SCSCR. Each interrupt request is sent separately to the interrupt controller.

TXI is requested when the TDRE bit in the SCSSR is set to 1.

RXI is requested when the RDRF bit in the SCSSR is set to 1.

ERI is requested when the ORER, PER, or FER bit in the SCSSR is set to 1.

TEI is requested when the TEND bit in the SCSSR is set to 1. Where the TXI interrupt indicates that transmit data writing is enabled, the TEI interrupt indicates that the transmit operation is complete.

**Table 14.12 SCI Interrupt Sources**

| Interrupt Source | Description                       | Priority When Reset Is Cleared                                                    |
|------------------|-----------------------------------|-----------------------------------------------------------------------------------|
| ERI              | Receive error (ORER, PER, or FER) | High                                                                              |
| RXI              | Receive data full (RDRF)          |  |
| TXI              | Transmit data empty (TDRE)        |                                                                                   |
| TEI              | Transmit end (TEND)               | Low                                                                               |

See section 4, Exception Processing, for information on the priority order and relationship to non-SCI interrupts.

## 14.6 Usage Note

Note the following points when using the SCI.

**SCTDR Writing to and TDRE Flag:** The TDRE bit in SCSSR is a status flag indicating loading of transmit data from the SCTDR into the SCTSR. The SCI sets TDRE to 1 when it transfers data from the SCTDR to the SCTSR. Data can be written to the SCTDR regardless of the TDRE bit state. If new data is written in the SCTDR when TDRE is 0, however, the old data stored in the SCTDR will be lost because the data has not yet been transferred to the SCTSR. Before writing transmit data to the SCTDR, be sure to check that TDRE is set to 1.

**Simultaneous Multiple Receive Errors:** Table 14.13 indicates the state of the SCSSR status flags when multiple receive errors occur simultaneously. When an overrun error occurs, the SCRSR contents cannot be transferred to the SCRDR, so receive data is lost.

**Table 14.13 SCSSR Status Flags and Transfer of Receive Data**

| Receive Error Status                         | SCSSR Status Flags |      |     |     | Receive Data Transfer<br>SCRSR → SCRDR |
|----------------------------------------------|--------------------|------|-----|-----|----------------------------------------|
|                                              | RDRF               | ORER | FER | PER |                                        |
| Overrun error                                | 1                  | 1    | 0   | 0   | X                                      |
| Framing error                                | 0                  | 0    | 1   | 0   | O                                      |
| Parity error                                 | 0                  | 0    | 0   | 1   | O                                      |
| Overrun error + framing error                | 1                  | 1    | 1   | 0   | X                                      |
| Overrun error + parity error                 | 1                  | 1    | 0   | 1   | X                                      |
| Framing error + parity error                 | 0                  | 0    | 1   | 1   | O                                      |
| Overrun error + framing error + parity error | 1                  | 1    | 1   | 1   | X                                      |

Notes: X: Receive data is not transferred from SCRSR to SCRDR.

O: Receive data is transferred from SCRSR to SCRDR.

**Break Detection and Processing:** Break signals can be detected by reading the RxD0 pin directly when a framing error (FER) is detected. In the break state, the input from the RxD0 pin consists of all 0s, so FER is set and the parity error flag (PER) may also be set. In the break state, the SCI receiver continues to operate, so if the FER bit is cleared to 0, it will be set to 1 again.

**Sending a Break Signal:** The TxD0 pin I/O condition and level can be determined by means of the SCP0DT bit of the SCPDR and bits SCP0MD0 and SCP0MD1 of the SCPDR. These bits can be used to send breaks. To send a break during serial transmission, clear the SCP0DT bit to 0 (designating low level), then clear the TE bit to 0 (halting transmission). When the TE bit is cleared to 0, the transmitter is initialized regardless of the current transmission state, and 0 is output from the TxD0 pin.

**TEND Flag and TE Bit Processing:** The TEND flag is set to 1 during transmission of the stop bit of the last data. Consequently, if the TE bit is cleared to 0 immediately after setting of the TEND flag has been confirmed, the stop bit will be in the process of transmission and will not be transmitted normally. Therefore, the TE bit should not be cleared to 0 for at least 0.5 serial clock cycles (or 1.5 cycles if two stop bits are used) after setting of the TEND flag setting is confirmed.

**Receive Error Flags and Transmitter Operation (Clock Synchronous Mode Only):** When a receive error flag (ORER, PER, or FER) is set to 1, the SCI will not start transmitting even if TDRE is set to 1. Be sure to clear the receive error flags to 0 before starting to transmit. Note that clearing RE to 0 does not clear the receive error flags.

**Receive Data Sampling Timing and Receive Margin in the Asynchronous Mode:** In the asynchronous mode, the SCI operates on a base clock of 16 times the transfer rate frequency. In receiving, the SCI synchronizes internally with the falling edge of the start bit, which it samples on the base clock. Receive data is latched on the rising edge of the eighth base clock pulse (figure 14.24).

**Figure 14.24 Receive Data Sampling Timing in Asynchronous Mode**

The receive margin in the asynchronous mode can therefore be expressed as in equation 1.

Equation 1:

$$M = \left| \left( 0.5 - \frac{1}{2N} \right) - (L - 0.5)F - \frac{|D - 0.5|}{N} (1 + F) \right| \times 100\%$$

Where:

M = Receive margin (%)

N = Ratio of clock frequency to bit rate (N = 16)

D = Clock duty cycle (D = 0–1.0)

L = Frame length (L = 9–12)

F = Absolute deviation of clock frequency

From equation 1, if F = 0 and D = 0.5, the receive margin is 46.875%, as in equation 2.

Equation 2:

$$\begin{aligned} M &= (0.5 - 1/(2 \times 16)) \times 100\% \\ &= 46.875\% \end{aligned}$$

This is a theoretical value. A reasonable margin to allow in system designs is 20 to 30%.

#### **Cautions for Clock Synchronous External Clock Mode:**

- Set TE = RE = 1 only when the external clock SCK0 is 1.
- Do not set TE = RE = 1 until at least four clocks after the external clock SCK0 has changed from 0 to 1.
- When receiving, RDRF is 1 when RE is set to zero 2.5–3.5 clocks after the rising edge of the SCK0 input of the D7 bit in RxD0, but it cannot be copied to SCRDR.

**Caution for Clock Synchronous Internal Clock Mode:** In the receiving, RDRF become 1 when RE is set to 0, 1.5 clocks after the rising edge of the SCK0 output of the D7 bit in RxD0, but it cannot be copied to SCRDR.

## Section 15 Smart Card Interface

As an added serial communications interface function, the SCI supports an IC card (smart card) interface that conforms to the data transfer protocol (asynchronous half-duplex character transmission protocol) of the ISO/IEC standard 7816-3 for identification of cards. Register settings are used to switch between the ordinary serial communication interface and the smart card interface. Figure 15.1 is the block diagram of the smart card interface.

## 15.1 Feature

The smart card interface has the following features:

- Asynchronous mode
  - Data length: Eight bits
  - Parity bit generation and check
  - Receive mode error signal detection (parity error)
  - Transmit mode error signal detection and automatic re-transmission of data
  - Supports both direct convention and inverse convention
- Bit rate can be selected using on-chip baud rate generator.
- Three types of interrupts: Transmit-data-empty, receive-data-full, and communication-error interrupts are requested independently.

### Figure 15.1 Smart Card Interface Block Diagram

## 15.2 Input/Output Pin

Table 15.1 summarizes the smart card interface pins.

**Table 15.1 Pin Configuration**

| Pin Name          | Abbreviation | I/O    | Function             |
|-------------------|--------------|--------|----------------------|
| Serial clock pin  | SCK0         | Output | Clock output         |
| Receive data pin  | RxD0         | Input  | Receive data input   |
| Transmit data pin | TxD0         | Output | Transmit data output |

## 15.3 Register Description

The smart card interface has the following registers.

The SCSCMR, SCBRR, SCSCR, SCTDR, and SCRDR registers are the same as those of the SCI. So see the register description in section 14, Serial Communication Interface.

Refer to see section 23, List of Registers, for more details of the addresses and access sizes.

- Smart card mode register (SCSCMR)
- Serial status register (SCSSR)
- Serial mode register (SCSMR)
- Bit rate register (SCBRR)
- Serial control register (SCSCR)
- Transmit data register (SCTDR)
- Receive data register (SCRDR)

### 15.3.1 Smart Card Mode Register (SCSCMR)

The smart card mode register (SCSCMR) is an 8-bit read/write register that selects smart card interface functions.

| Bit    | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------|----------|---------------|-----|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7 to 4 | —        | —             | R   | Reserved<br>An undefined value are read from these bits.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

### 15.3.2 Serial Status Register (SCSSR)

In the smart card interface mode, the function of bit 4 in SCSSR of the SCI is changed as shown below. Relating to this, the setting conditions for bit 2, the TEND bit, are also changed.

| Bit | Bit Name | Initial Value | R/W    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----|----------|---------------|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7   | TDRE     | 1             | R/(W)* | Transmit Data Register Empty                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 6   | RDRF     | 0             | R/(W)* | Receive Register Full                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 5   | ORER     | 0             | R/(W)* | Overrun Error                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|     |          |               |        | These bits have the same function as in the ordinary SCI. See section 14, Serial Communication Interface (SCI), for more information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 4   | ERS      | 0             | R/(W)* | <p>Error Signal Status</p> <p>In the smart card interface mode, bit 4 indicates the state of the error signal returned from the receiving side during transmission. The smart card interface cannot detect framing errors.</p> <p>0: Receiving ended normally with no error signal.</p> <p>[Clearing conditions]</p> <ol style="list-style-type: none"><li>1. The chip is reset or enters standby mode.</li><li>2. ERS is read as 1, then written to with 0.</li></ol> <p>1: An error signal indicating a parity error was transmitted from the receiving side.</p> <p>[Setting condition]</p> <p>The error signal sampled is low.</p> <p>Note: The ERS flag maintains its state even when the TE bit in SCSCR is cleared to 0.</p> |

| Bit | Bit Name | Initial Value | R/W    | Description                 |
|-----|----------|---------------|--------|-----------------------------|
| 3   | PER      | 0             | R/(W)* | Parity error                |
| 2   | TEND     | 1             | R      | Transmission end            |
| 1   | MPB      | 0             | R      | Multiprocessor bit          |
| 0   | MPBT     | 0             | R/W    | Multiprocessor bit transfer |

These bits have the same function as in the ordinary SCI. See section 14, Serial Communication Interface (SCI), for more information. The setting conditions for bit 2, the transmit end bit (TEND), are changed as follows.

0: Transmission is in progress.

[Clearing condition]

TDRE is read as 1, then written to with 0.

1: End of transmission.

[Setting conditions]

1. The chip is reset or enters standby mode.
2. TE bit in SCSCR is 0 and the FER/ERS bit is also 0.
3.  $C/\bar{A}$  bit in SCSMR is 0, and TDRE = 1 and FER/ERS = 0 (normal transmission) 2.5 etu after a one-byte serial character is transmitted.
4.  $C/\bar{A}$  bit in SCSMR is 1, and TDRE = 1 and FER/ERS = 0 (normal transmission) 1.0 etu after a one-byte serial character is transmitted.

Note: etu is an abbreviation of elementary time unit, which is the period for the transfer of 1 bit.

---

Note: \* Only 0 can be written, to clear the flag.

## 15.4 Operation

### 15.4.1 Overview

The primary functions of the smart card interface are described below.

1. Each frame consists of 8-bit data and a parity bit.
2. During transmission, the card leaves a guard time of at least 2 etu (elementary time units: the period for 1 bit to transfer) from the end of the parity bit to the start of the next frame.
3. During reception, the card outputs an error signal low level for 1 etu after 10.5 etu has elapsed from the start bit if a parity error was detected.
4. During transmission, it automatically transmits the same data after allowing at least 2 etu from the time the error signal is sampled.
5. Only start-stop type asynchronous communication functions are supported; no synchronous communication functions are available.

### 15.4.2 Pin Connections

Figure 15.2 shows the pin connection diagram for the smart card interface. During communication with an IC card, transmission and reception are both carried out over the same data transfer line, so connect the TxD $\phi$  and RxD $\phi$  pins on the chip. Pull up the data transfer line to the power supply V<sub>CC</sub> side with a resistor.

When using the clock generated by the smart card interface on an IC card, input the SCK $\phi$  pin output to the IC card's CLK pin. This connection is not necessary when the internal clock is used on the IC card.

Use the chip's port output as the reset signal. Apart from these pins, the power and ground pin connections are usually also required.

**Note:** When the IC card is not connected and both RE and TE are set to 1, closed communication is possible and self-diagnosis can be performed.

**Figure 15.2 Pin Connection Diagram for the Smart Card Interface**

### 15.4.3 Data Format

Figure 15.3 shows the data format for the smart card interface. In this mode, parity is checked every frame while receiving and error signals sent to the transmitting side whenever an error is detected so that data can be re-transmitted. During transmission, if an error signal is sampled, the same data is re-transmitted.

**Figure 15.3 Data Format for Smart Card Interface**

The operating sequence is:

1. The data line is high impedance when not in use and is fixed high with a pull-up resistor.
2. The transmitting side starts one frame of data transmission. The data frame starts with a start bit (Ds, low level). The start bit is followed by eight data bits (D0 to D7) and a parity bit (Dp).
3. On the smart card interface, the data line returns to high impedance after this. The data line is pulled high with a pull-up resistor.
4. The receiving side checks parity. When the data is received normally with no parity errors, the receiving side then waits to receive the next data. When a parity error occurs, the receiving side outputs an error signal (DE, low level) and requests re-transfer of data. The receiving station returns the signal line to high impedance after outputting the error signal for a specified period. The signal line is pulled high with a pull-up resistor.
5. The transmitting side transmits the next frame of data unless it receives an error signal. If it does receive an error signal, it returns to step 2 to re-transmit the erroneous data.

#### 15.4.4 Register Settings

Table 15.2 shows the bit map of the registers that the smart card interface uses. Bits shown as 1 or 0 must be set to the indicated value. The settings for the other bits are described below.

**Table 15.2 Register Settings for the Smart Card Interface**

| Register | Address     | Bit 7             | Bit 6 | Bit 5 | Bit 4             | Bit 3 | Bit 2 | Bit 1 | Bit 0 |
|----------|-------------|-------------------|-------|-------|-------------------|-------|-------|-------|-------|
| SCSMR    | H'FFFFFFE80 | C/ $\overline{A}$ | 0     | 1     | O/ $\overline{E}$ | 1     | 0     | CKS1  | CKS0  |
| SCBRR    | H'FFFFFFE82 | BRR7              | BRR6  | BRR5  | BRR4              | BRR3  | BRR2  | BRR1  | BRR0  |
| SCSCR    | H'FFFFFFE84 | TIE               | RIE   | TE    | RE                | 0     | 0     | CKE1  | CKE0  |
| SCTDR    | H'FFFFFFE86 | TDR7              | TDR6  | TDR5  | TDR4              | TDR3  | TDR2  | TDR1  | TDR0  |
| SCSSR    | H'FFFFFFE88 | TDRE              | RDRF  | ORER  | FER/<br>ERS       | PER   | TEND  | 0     | 0     |
| SCRDR    | H'FFFFFFE8A | RDR7              | RDR6  | RDR5  | RDR4              | RDR3  | RDR2  | RDR1  | RDR0  |
| SCSCMR   | H'FFFFFFE8C | —                 | —     | —     | —                 | SDIR  | SINV  | —     | SMIF  |

Note: Dashes indicate unused bits.

1. Setting the serial mode register (SCSMR): The C/ $\overline{A}$  bit selects the set timing of the TEND flag, and selects the clock output state with the combination of bits CKE1 and CKE0 in the SCSCR. Set the O/ $\overline{E}$  bit to 0 when the IC card uses the direct convention or to 1 when it uses the inverse convention. Select the on-chip baud rate generator clock source with the CKS1 and CKS0 bits (see section 15.4.5, Clock).
2. Setting the bit rate register (SCBRR): Set the bit rate. See section 15.4.5, Clock, to see how to calculate the set value.

3. Setting the serial control register (SCSCR): The TIE, RIE, TE and RE bits function as they do for the ordinary SCI. See section 14, Serial Communication Interface (SCI), for more information. The CKE0 bit specifies the clock output. When no clock is output, set 0; when a clock is output, set 1.
4. Setting the smart card mode register (SCSCMR): The SDIR and SINV bits are both set to 0 for IC cards that use the direct convention and both to 1 when the inverse convention is used. The SMIF bit is set to 1 for the smart card interface.

Figure 15.4 shows sample waveforms for register settings of the two types of IC cards (direct convention and inverse convention) and their start characters.

In the direct convention type, the logical 1 level is state Z, the logical 0 level is state A, and communication is LSB first. The start character data is H'3B. The parity bit is even (as specified in the smart card standards), and thus 1.

In the inverse convention type, the logical 1 level is state A, the logical 0 level is state Z, and communication is MSB first. The start character data is H'3F. The parity bit is even (as specified in the smart card standards), and thus 0, which corresponds to state Z.

Only data bits D7 to D0 are inverted by the SINV bit. To invert the parity bit, set the  $O/\bar{E}$  bit in SCSCMR to odd parity mode. This applies to both transmission and reception.

**Figure 15.4 Waveform of Start Character**

## 15.4.5 Clock

Only the internal clock generated by the on-chip baud rate generator can be used as the communication clock in the smart card interface. The bit rate for the clock is set by the SCBRR and the CKS1 and CKS0 bits in the SCSMR, and is calculated using the equation below. Table 15.4 shows sample bit rates. If clock output is then selected by setting CKE0 to 1, a clock with a frequency 372 times the bit rate is output from the SCK0 pin.

$$B = \frac{P\phi}{1488 \times 2^{2n-1} \times (N + 1)} \times 10^6$$

Where:

N = Value set in SCBRR ( $0 \leq N \leq 255$ )

B = Bit rate (bit/s)

Pφ = Peripheral module operating frequency (MHz)

n = 0 to 3 (table 15.3)

**Table 15.3 Relationship of n to CKS1 and CKS0**

| n | CKS1 | CKS0 |
|---|------|------|
| 0 | 0    | 0    |
| 1 | 0    | 1    |
| 2 | 1    | 0    |
| 3 | 1    | 1    |

**Table 15.4 Examples of Bit Rate B (Bit/s) for SCBRR Settings (n = 0)**

| N | Pφ (MHz) |         |         |         |         |         |         |
|---|----------|---------|---------|---------|---------|---------|---------|
|   | 7.1424   | 10.00   | 10.7136 | 13.00   | 14.2848 | 16.00   | 18.00   |
| 0 | 9600.0   | 13440.9 | 14400.0 | 17473.1 | 19200.0 | 21505.4 | 24193.5 |
| 1 | 4800.0   | 6720.4  | 7200.0  | 8736.6  | 9600.0  | 10752.7 | 12096.8 |
| 2 | 3200.0   | 4480.3  | 4800.0  | 5824.4  | 6400.0  | 7168.5  | 8064.5  |

Note: The bit rate is rounded to two decimal places.

Calculate the value to be set in the bit rate register (SCBRR) from the operating frequency and the bit rate. N is an integer in the range  $0 \leq N \leq 255$ , specifying a smallish error.

$$N = \frac{P\phi}{1488 \times 2^{2n-1} \times B} \times 10^6 - 1$$

**Table 15.5 Examples of SCBRR Settings for Bit Rate B (Bit/s) (n = 0)**

| $\phi$ (MHz) (9600 Bits/s) |       |       |       |         |       |       |       |         |       |       |       |
|----------------------------|-------|-------|-------|---------|-------|-------|-------|---------|-------|-------|-------|
| 7.1424                     |       | 10.00 |       | 10.7136 |       | 13.00 |       | 14.2848 |       | 16.00 |       |
| N                          | Error | N     | Error | N       | Error | N     | Error | N       | Error | N     | Error |
| 0                          | 0.00  | 1     | 30.00 | 1       | 25.00 | 1     | 8.99  | 1       | 0.00  | 1     | 12.01 |
| 2                          | 15.99 |       |       |         |       |       |       |         |       |       |       |

**Table 15.6 Maximum Bit Rates for Frequencies (Smart Card Interface Mode)**

| P $\phi$ (MHz) | Maximum Bit Rate (Bit/s) | N | n |
|----------------|--------------------------|---|---|
| 7.1424         | 9600                     | 0 | 0 |
| 10.00          | 13441                    | 0 | 0 |
| 10.7136        | 14400                    | 0 | 0 |
| 13.00          | 17473                    | 0 | 0 |
| 14.2848        | 19200                    | 0 | 0 |
| 16.00          | 21505                    | 0 | 0 |
| 18.00          | 24194                    | 0 | 0 |

The bit rate error is found as follows:

$$\text{Error (\%)} = \left( \frac{P\phi}{1488 \times 2^{2n-1} \times B \times (N + 1)} \times 10^6 - 1 \right) \times 100$$

Table 15.5 shows example settings of SCBRR, and table 15.6 shows the maximum bit rate for each frequency.

Table 15.7 shows the relationship between transmit/receive clock register set values and output states on the smart card interface.

**Table 15.7 Register Set Values and SCK $\phi$  Pin**

| Setting         | Register Value |              |      |      | SCK Pin                                                                           |                                                                 |
|-----------------|----------------|--------------|------|------|-----------------------------------------------------------------------------------|-----------------------------------------------------------------|
|                 | SMIF           | C/ $\bar{A}$ | CKE1 | CKE0 | Output                                                                            | State                                                           |
| 1* <sup>1</sup> | 1              | 0            | 0    | 0    | Port                                                                              | Determined by setting of port register SCP1MD1 and SCP1MD0 bits |
|                 | 1              | 0            | 0    | 1    |  | SCK0 (serial clock) output state                                |
| 2* <sup>2</sup> | 1              | 1            | 0    | 0    | Low output                                                                        | Low output state                                                |
|                 | 1              | 1            | 0    | 1    |  | SCK0 (serial clock) output state                                |
| 3* <sup>2</sup> | 1              | 1            | 1    | 0    | High output                                                                       | High output state                                               |
|                 | 1              | 1            | 1    | 1    |  | SCK0 (serial clock) output state                                |

- Notes: 1. The SCK0 output state changes as soon as the CKE0 bit is modified. The CKE1 bit should be cleared to 0.
2. The clock duty remains constant despite stopping and starting of the clock by modification of the CKE0 bit.

#### 15.4.6 Data Transmission and Reception

**Initialization:** Initialize the SCI using the following procedure before sending or receiving data. Initialization is also required for switching from transmit mode to receive mode or from receive mode to transmit mode. Figure 15.5 shows an example of initialization process flowchart.

1. Clear TE and RE in SCSCR to 0.
2. Clear error flags FER/ERS, PER, and ORER to 0 in SCSSR.
3. Set the C/ $\bar{A}$  bit, parity bit (O/ $\bar{E}$  bit), and baud rate generator select bits (CKS1 and CKS0 bits) in SCSMR. At this time also clear the CHR and MP bits to 0 and set the STOP and PE bits to 1.
4. Set the SMIF, SDIR, and SINV bits in SCSCMR. When the SMIF bit is set to 1, the TxD and RxD pins both switch from ports to SCI pins and become high impedance.
5. Set the value corresponding to the bit rate in SCBRR.
6. Set the clock source select bits (CKE1 and CKE0 bits) in SCSCR. Clear the TIE, RIE, TE, RE, MPIE, and TEIE bits to 0. When the CKE0 bit is set to 1, a clock is output from the SCK $\phi$  pin.
7. After waiting at least 1 bit, set the TIE, RIE, TE, and RE bits in SCSCR. Do not set the TE and RE bits simultaneously unless performing self-diagnosis.

**Figure 15.5 Initialization Flowchart (Example)**

**Serial Data Transmission:** The processing procedures in the smart card mode differ from ordinary SCI processing because data is retransmitted when an error signal is sampled during a data transmission. An example of transmission processing flowchart is shown in figure 15.6.

1. Initialize the smart card interface mode as described in Initialization above.
2. Check that the FER/ERS bit in SCSSR is cleared to 0.
3. Repeat steps 2 and 3 until the TEND flag in SCSSR is set to 1.
4. Write the transmit data into SCTDR, clear the TDRE flag to 0 and start transmitting. The TEND flag will be cleared to 0.
5. To transmit more data, return to step 2.
6. To end transmission, clear the TE bit to 0.

This processing can be interrupted. When the TIE bit is set to 1 and interrupt requests are enabled, a transmit-data-empty interrupt (TXI) will be requested when the TEND flag is set to 1 at the end of the transmission. When the RIE bit is set to 1 and interrupt requests are enabled, a communication error interrupt (ERI) will be requested when the ERS flag is set to 1 when an error occurs in transmission. See Interrupt Operation below for more information.

**Figure 15.6 Transmission Flowchart**

**Serial Data Reception:** The processing procedures in the smart card mode are the same as in ordinary SCI processing. The reception processing flowchart is shown in figure 15.7.

1. Initialize the smart card interface mode as described above in Initialization and in figure 15.5.
2. Check that the ORER and PER flags in SCSSR are cleared to 0. If either flag is set, clear both to 0 after performing the appropriate error processing procedures.
3. Repeat steps 2 and 3 until the RDRF flag is set to 1.
4. Read the receive data from SCRDR.
5. To receive more data, clear the RDRF flag to 0 and return to step 2.
6. To end reception, clear the RE bit to 0.

This processing can be interrupted. When the RIE bit is set to 1 and interrupt requests are enabled, a receive-data-full interrupt (RXI) will be requested when the RDRF flag is set to 1 at the end of the reception. When an error occurs during reception and either the ORER or PER flag is set to 1, a communication error interrupt (ERI) will be requested. See Interrupt Operation below for more information.

The received data will be transferred to SCRDR even when a parity error occurs during reception and PER is set to 1, so this data can still be read.

**Figure 15.7 Reception Flowchart (Example)**

**Switching Modes:** When switching from receive mode to transmit mode, check that the receive operation is completed before starting initialization and setting RE to 0 and TE to 1. The RDRF, PER, and ORER flags can be used to check if reception is completed. When switching from transmit mode to receive mode, check that the transmit operation is completed before starting initialization and setting TE to 0 and RE to 1. The TEND flag can be used to check if transmission is completed.

**Interrupt Operation:** In the smart card interface mode, there are three types of interrupts: transmit-data-empty (TXI), communication error (ERI) and receive-data-full (RXI). In this mode, the transmit-end interrupt (TEI) cannot be requested.

Set the TEND flag in SCSSR to 1 to request a TXI interrupt. Set the RDRF flag in SCSSR to 1 to request an RXI interrupt. Set the ORER, PER, or FER/ERS flag in SCSSR to 1 to request an ERI interrupt (table 15.8).

**Table 15.8 Smart Card Mode Operating State and Interrupt Sources**

| Mode          | State  | Flag         | Mask Bit | Interrupt Source |
|---------------|--------|--------------|----------|------------------|
| Transmit mode | Normal | TEND         | TIE      | TXI              |
|               | Error  | FER/ERS      | RIE      | ERI              |
| Receive mode  | Normal | RDRF         | RIE      | RXI              |
|               | Error  | PER,<br>ORER | RIE      | ERI              |

## 15.5 Usage Note

When the SCI is used as a smart card interface, be sure that all criteria in sections 15.4.1 and 15.4.2 are applied.

### Receive Data Timing and Receive Margin in Asynchronous Mode:

In asynchronous mode, the SCI runs on a basic clock with a frequency of 372 times the transfer rate. During reception, the SCI samples the falling of the start bit using the base clock to achieve internal synchronization. Receive data is latched internally on the rising edge of the 186th basic clock cycle (figure 15.8).

**Figure 15.8 Receive Data Sampling Timing in Smart Card Mode**

The receive margin is found from the following equation:

For smart card mode:

$$M = \left| \left( 0.5 - \frac{1}{2N} \right) - (L - 0.5)F - \frac{|D - 0.5|}{N} (1 + F) \right| \times 100\%$$

Where:

M = Receive margin (%)

N = Ratio of bit rate to clock (N = 372)

D = Clock duty (D = 0 to 1.0)

L = Frame length (L = 10)

F = Absolute value of clock frequency deviation

Using this equation, the receive margin when F = 0 and D = 0.5 is as follows:

$$M = (0.5 - 1/2 \times 372) \times 100\% = 49.866\%$$

## Retransmission (Receive and Transmit Modes):

**Retransmission by the SCI in Receive Mode:** Figure 15.9 shows the retransmission operation in the SCI receive mode.

1. When the received parity bit is checked and an error is found, the PER bit in SCSSR is automatically set to 1. If the RIE bit in SCSCR is enabled at this time, an ERI interrupt is requested. Be sure to clear the PER bit before the next parity bit is sampled.
2. The RDRF bit in SCSSR is not set in the frame that caused the error.
3. When the received parity bit is checked and no error is found, the PER bit in SCSSR is not set.
4. When the received parity bit is checked and no error is found, reception is considered to have been completed normally and the RDRF bit in SCSSR is automatically set to 1. If the RIE bit in SCSCR is enabled at this time, an RXI interrupt is requested.
5. When a normal frame is received, the pin maintains a three-state state when it transmits the error signal.

**Figure 15.9 Retransmission in SCI Receive Mode**

**Retransmission by the SCI in Transmit Mode:** Figure 15.10 shows the retransmission operation in the SCI transmit mode.

1. After transmission of one frame is completed, the FER/ERS bit in SCSSR is set to 1 when an error signal is returned from the receiving side. If the RIE bit in SCSCR is enabled at this time, an ERI interrupt is requested. Be sure to clear the FER/ERS bit before the next parity bit is sampled.
2. The TEND bit in SCSSR is not set in the frame that received the error signal that indicated the error.
3. The FER/ERS bit in SCSSR is not set when no error signal is returned from the receiving side.
4. When no error signal is returned from the receiving side, the TEND bit in SCSSR is set to 1 when the transmission of the frame that includes the retransmission is considered completed. If the TIE bit in SCSCR is enabled at this time, a TXI interrupt will be requested.

**Figure 15.10 Retransmission in SCI Transmit Mode**

### Support for Block Transfer Mode :

This smart card interface conforms to the T = 0 (character transfer) protocols of ISO/IEC7816-3. As a result, this smart card interface does not support block transfer, in which error signals are neither sent nor detected, and data is not automatically retransmitted.

# Section 16 Serial Communication Interface with FIFO (SCIF)

This LSI has single-channel serial communication interface with FIFO (SCIF) that supports asynchronous serial communication. It also has 16-stage FIFO registers for both transfer and receive that enables this LSI efficient high-speed continuous communication. Figure 16.1 shows a diagram of the SCIF, and figures 16.2 to 16.4 show the I/O ports.

## 16.1 Feature

- Asynchronous serial communication:
  - Serial data communications are performed by start-stop in character units. The SCI can communicate with a universal asynchronous receiver/transmitter (UART), an asynchronous communication interface adapter (ACIA), or any other communications chip that employs a standard asynchronous serial system. There are eight selectable serial data communication formats.
  - Data length: Seven or eight bits
  - Stop bit length: One or two bits
  - Parity: Even, odd, or none
  - Receive error detection: Parity and framing errors
  - Break detection:
- Full duplex communication: The transmitting and receiving sections are independent, so the SCI can transmit and receive simultaneously. Both sections use 16-stage FIFO buffering, so high-speed continuous data transfer is possible in both the transmit and receive directions.
- On-chip baud rate generator with selectable bit rates
- Internal or external transmit/receive clock source: From either baud rate generator (internal) or SCK2 pin (external)
- Four types of interrupts: Transmit-FIFO-data-empty, break, receive-FIFO-data-full, and receive-error interrupts are requested independently. The direct memory access controller (DMAC) can be activated to execute a data transfer by a transmit-FIFO-data-empty or receive-FIFO-data-full interrupt.
- When the SCIF is not in use, it can be stopped by halting the clock supplied to it, saving power.
- On-chip modem control functions ( $\overline{\text{RTS2}}$  and  $\overline{\text{CTS2}}$ )
- The quantity of data in the transmit and receive FIFO registers and the number of receive errors of the receive data in the receive FIFO register can be known.
- The time-out error (DR) can be detected in receiving.

**Figure 16.1 SCIF Block Diagram**

**Figure 16.3 SCPT[2]/TxD2 Pin**

**Figure 16.4 SCPT[2]/Rx2D Pin**

## 16.2 Input/Output Pin

The SCIF has the I/O pins summarized in table 16.1.

**Table 16.1 SCIF Pins**

| Pin Name            | Abbreviation             | I/O    | Function             |
|---------------------|--------------------------|--------|----------------------|
| Serial clock pin    | SCK2                     | I/O    | Clock I/O            |
| Receive data pin    | RxD2                     | Input  | Receive data input   |
| Transmit data pin   | TxD2                     | Output | Transmit data output |
| Request to send pin | $\overline{\text{RTS2}}$ | Output | Request to send      |
| Clear to send pin   | $\overline{\text{CTS2}}$ | Input  | Clear to send        |

## 16.3 Register Description

SCIF has the registers listed below. These registers specify the data format and bit rate, and control the transmitter and receiver sections.

Refer to section 23, List of Registers, for more details of the addresses and access sizes.

- Serial mode register 2 (SCSMR2)
- Bit rate register 2 (SCBRR2)
- Serial control register 2 (SCSCR2)
- Transmit FIFO data register 2 (SCFTDR2)
- Serial status register 2 (SCSSR2)
- Receive data FIFO register 2 (SCFRDR2)
- FIFO control register 2 (SCFCR2)
- FIFO data count set register 2 (SCFDR2)
- SC port control register (SCPCR)
- SC port data register (SCPDR)

### 16.3.1 Receive Shift Register 2 (SCRSR2)

The receive shift register 2 (SCRSR2) is an eight-bit register that receives serial data. The CPU cannot read from or write to the SCRSR2 directly. Data input at the RxD pin is loaded into the SCRSR2 in the order received, LSB (bit 0) first, converting the data to parallel form. When one byte has been received, it is automatically transferred to the SCFRDR2, which is a receive FIFO register.

### 16.3.2 Receive FIFO Data Register 2 (SCFRDR2)

The 16-byte receive FIFO data register2(SCFRDR2) stores serial receive data. The SCIF completes the reception of one byte of serial data by moving the received data from the SCRSR2 into the SCFRDR2 for storage. Continuous receive is possible until 16 bytes are stored.

The CPU can read but not write the SCFRDR2. When data is read without received data in the SCFRDR2, the value is undefined. When the received data in this register becomes full, the subsequent serial data is lost.

### 16.3.3 Transmit Shift Register 2 (SCTSR2)

The transmit shift register 2 (SCTSR2) is an eight-bit register that transmits serial data. The CPU cannot read from or write to the SCTSR2 directly. The SCI loads transmit data from the SCFTDR2 into the SCTSR2, then transmits the data serially from the TxD pin, LSB (bit 0) first. After transmitting one data byte, the SCI automatically loads the next transmit data from the SCFTDR2 into the SCTSR2 and starts transmitting again.

### 16.3.4 Transmit FIFO Data Register 2 (SCFTDR2)

The transmit FIFO data register 2 (SCFTDR2) is a 16-byte FIFO register that stores data for serial transmission. When the SCIF detects that the SCTSR is empty, it moves transmit data written in the SCFTDR2 into the SCTSR2 and starts serial transmission. Continuous serial transmission is performed until the transmit data in the SCFTDR2 becomes empty. The CPU can always write to the SCFTDR2.

When the transmit data in the SCFTDR2 is full (16 bytes), next data cannot be written. If attempted to write, the data is ignored.

### 16.3.5 Serial Mode Register 2 (SCSMR2)

The serial mode register2 (SCSMR2) is an eight-bit register that specifies the SCIF serial communication format and selects the clock source for the baud rate generator.

The CPU can always read and write the SCSMR2.

| Bit | Bit Name     | Initial Value | R/W | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----|--------------|---------------|-----|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### 16.3.6 Serial Control Register 2 (SCSCR2)

The serial control register 2 (SCSCR2) operates the SCI transmitter/receiver, selects the serial clock output in the asynchronous mode, enables/disables interrupt requests, and selects the transmit/receive clock source. The CPU can always read and write the SCSCR2.

| Bit | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

16.3.7 Serial Status Register 2 (SCSSR2)

The serial status register 2 (SCSSR2) is a 16-bit register. The upper 8 bits indicate the number of receive errors in the data of the SCFRDR2, and the lower 8 bits indicate SCIF operating state.

The CPU can always read and write the SCSSR2, but cannot write 1 to the status flags (ER, TEND, TDFE, BRK, OPER, and DR). These flags can be cleared to 0 only if they have first been read (after being set to 1). Bits 3 (FER) and 2 (PER) are read-only bits and cannot be written.

If attempted to read after all data in the SCFRDR2 have been read, the data is undefined. The quantity of receive data in SCFRDR2 is indicated by the lower 8 bits of SCFTDR2.</p> |

| Bit | Bit Name | Initial Value | R/W    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----|----------|---------------|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0   | DR       | 0             | R/(W)* | <p>Receive Data Ready</p> <p>Indicates that the SCFRDR2 stores the data which is less than the specified number of receive triggers, and that next data is not yet received after 15 etu has elapsed from the last stop bit.</p> <p>0: Receive is in progress, or no received data remains in SCFRDR2 after the receive ended normally.</p> <p>[Clearing conditions]</p> <ol style="list-style-type: none"> <li>1. The chip is power-on reset or enters standby mode.</li> <li>2. DR is read as 1, then written to with 0.</li> </ol> <p>1: Next receive data is not received.</p> <p>[Setting condition]</p> <p>SCFRDR2 stores the data which is less than the specified number of receive triggers, and that next data is not yet received after 15 etu has elapsed from the last stop bit.*</p> <p>Note: * This is equivalent to 1.5 frames with the 8-bit 1-stop-bit format. (etu: Element Time Unit)</p> |

---

Note: \* The only value that can be written is 0 to clear the flag.

16.3.8 Bit Rate Register 2 (SCBRR2)

The bit rate register 2 (SCBRR2) is an eight-bit register that, together with the baud rate generator clock source selected by the CKS1 and CKS0 bits in the SCSMR2, determines the serial transmit/receive bit rate.

The CPU can always read and write the SCBRR2. The SCBRR2 is initialized to H'FF by a reset or in module standby or standby mode. Each channel has independent baud rate generator control, so different values can be set in two channels.

The SCBRR2 setting is calculated as follows:

Asynchronous mode:

$$N = \frac{P\phi}{64 \times 2^{2n-1} \times B} \times 10^6 - 1$$

- B: Bit rate (bit/s)
- N: SCBRR2 setting for baud rate generator (0 ≤ N ≤ 255)
- Pφ: Operating frequency for peripheral modules (MHz)
- n: Baud rate generator clock source (n = 0, 1, 2, 3) (for the clock sources and values of n, see table 16.2.)

Table 16.2 SCSMR2 Settings

| n | Clock Source | SCSMR2 Settings |      |
|---|--------------|-----------------|------|
|   |              | CKS1            | CKS0 |
| 0 | Pφ           | 0               | 0    |
| 1 | Pφ/4         | 0               | 1    |
| 2 | Pφ/16        | 1               | 0    |
| 3 | Pφ/64        | 1               | 1    |

Note: Find the bit rate error by the following formula:

$$\text{Error (\%)} = \left\{ \frac{P\phi \times 10^6}{(N+1) \times 64 \times 2^{2n-1} \times B} - 1 \right\} \times 100$$

Table 16.3 lists examples of SCBRR2 settings.

**Table 16.3 Bit Rates and SCBRR2 Settings**

| Bit Rate (bit/s) | P $\phi$ (MHz) |     |           |   |     |           |        |     |           |

### 16.3.9 FIFO Control Register 2 (SCFCR2)

The FIFO control register 2 (SCFCR2) resets the number of data in the SCFTDR2 and SCFRDR2, sets the number of trigger data, and contains an enable bit for the loop back test. The SCFCR2 is always read and written by the CPU.

| Bit | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                                           |

### 16.3.10 FIFO Data Count Set Register 2 (SCFDR2)

The SCFDR2 is a 16-bit register which indicates the number of data stored in the SCFTDR2 and SCFRDR2. The SCFDR2 is always read from the CPU.

The upper eight bits of this register indicate the number of transmit data items stored in the SCFTDR2 that have not yet been transmitted. The H'00 means no transmit data, and the H'10 means that the full of transmit data are stored in the SCFTDR2.

The lower eight bits of this register indicate the number of receive data items stored in the SCFRDR2. The H'00 means no receive data, and the H'10 means that the full of receive data are stored in the SCFRDR2.

| Bit      | Bit Name | Initial Value | R/W | Description                                  |
|----------|----------|---------------|-----|----------------------------------------------|
| 15 to 13 | —        | 0             | R   | Reserved<br>These bits are always read as 0. |
| 12 to 8  | T4 to T0 | 0             | R   | Number of non-transmitted data.              |
| 7 to 5   | —        | 0             | R   | Reserved<br>These bits are always read as 0. |
| 4 to 0   | R4 to R0 | 0             | R   | Number of received data.                     |

### 16.3.11 SC Port Control Register (SCPCR)

For information about the SC port control register (SCPCR), see section 14.3.8, SC Port Control Register (SCPCR).

### 16.3.12 SC Port Data Register (SCPDR)

For information about the SC port data register (SCPDR), see section 14.3.9, SC Port Data Register (SCPDR).

## 16.4 Operation

For serial communication, the SCIF has an asynchronous mode in which characters are synchronized individually. Refer to section 14.4.1, Operation in Asynchronous Mode (SCI). The SCIF has the 16-byte FIFO buffer for both transmit and receive, reduces an overhead of the CPU, and enables continuous high-speed communication. Moreover, it has the  $\overline{\text{RTS2}}$  and  $\overline{\text{CTS2}}$  signals as the modem control signals. The transmission format is selected in the SCSMR2, as listed in table 16.6. The SCI clock source is selected by the combination of the CKE1 and CKE0 bits in SCSCR2, as listed in table 16.6.

- Data length is selectable: seven or eight bits.
- Parity and multiprocessor bits are selectable. So is the stop bit length (one or two bits). The combination of the preceding selections constitutes the communication format and character length.
- In receiving, it is possible to detect framing errors (FER), parity errors (PER), receive FIFO data full, receive data ready, and breaks.
- In transmitting, it is possible to detect transmit FIFO data empty.
- The number of stored data for both the transmit and receive FIFO registers is displayed.
- An internal or external clock can be selected as the SCIF clock source.
  - When an internal clock is selected, the SCIF operates using the on-chip baud rate generator, and can output a serial clock signal with a frequency 16 times the bit rate.
  - When an external clock is selected, the external clock input must have a frequency 16 times the bit rate. (The on-chip baud rate generator is not used.)

**Table 16.6 SCSMR2 Settings and SCIF Communication Formats**

### 16.4.1 Serial Operation

**Transmit/Receive Formats:** Table 16.8 lists eight communication formats that can be selected. The format is selected by settings in the SCSMR2.

**Table 16.8 Serial Communication Formats**

| SCSMR2 Bits |    |      | Serial Transmit/Receive Format and Frame Length |            |   |   |   |   |   |      |      |      |      |    |
|-------------|----|------|-------------------------------------------------|------------|---|---|---|---|---|------|------|------|------|----|
| CHR         | PE | STOP | 1                                               | 2          | 3 | 4 | 5 | 6 | 7 | 8    | 9    | 10   | 11   | 12 |
| 0           | 0  | 0    | START                                           | 8-Bit data |   |   |   |   |   |      | STOP |      |      |    |
| 0           | 0  | 1    | START                                           | 8-Bit data |   |   |   |   |   |      | STOP | STOP |      |    |
| 0           | 1  | 0    | START                                           | 8-Bit data |   |   |   |   |   |      | P    | STOP |      |    |
| 0           | 1  | 1    | START                                           | 8-Bit data |   |   |   |   |   |      | P    | STOP | STOP |    |
| 1           | 0  | 0    | START                                           | 7-Bit data |   |   |   |   |   | STOP |      |      |      |    |
| 1           | 0  | 1    | START                                           | 7-Bit data |   |   |   |   |   | STOP | STOP |      |      |    |
| 1           | 1  | 0    | START                                           | 7-Bit data |   |   |   |   |   | P    | STOP |      |      |    |
| 1           | 1  | 1    | START                                           | 7-Bit data |   |   |   |   |   | P    | STOP | STOP |      |    |

START: Start bit

STOP: Stop bit

P: Parity bit

**Clock:** An internal clock generated by the on-chip baud rate generator or an external clock input from the SCK2 pin can be selected as the SCIF transmit/receive clock. The clock source is selected by bits CKE1 and CKE0 in the serial control register (SCSCR2) (table 16.7).

When an external clock is input at the SCK2 pin, it must have a frequency equal to 16 times the desired bit rate.

When the SCIF operates on an internal clock, it can output a clock signal at the SCK2 pin. The frequency of this output clock is 16 times the bit rate.

**Transmitting and Receiving Data (SCIF Initialization):** Before transmitting or receiving, clear the TE and RE bits to 0 in the serial control register (SCSCR2), then initialize the SCIF as follows.

When changing the communication format, always clear the TE and RE bits to 0 before following the procedure given below. Clearing TE to 0 initializes the transmit shift register (SCTSR2).

Clearing TE and RE to 0, however, does not initialize the serial status register (SCSSR2), transmit FIFO data register (SCFTDR2), or receive FIFO data register (SCFRDR2), which retain their previous contents. Clear TE to 0 after all transmit data are transmitted and the TEND flag in the SCSSR2 is set. The transmitting data enters the high impedance state after clearing to 0 although the bit can be cleared to 0 in transmitting. Set the TFRST bit in the SCFCR2 to 1 and reset the SCFTDR2 before TE is set again to start transmission.

When an external clock is used, the clock should not be stopped during initialization or subsequent operation. SCIF operation becomes unreliable if the clock is stopped.

Figure 16.5 is a sample flowchart for initializing the SCIF. The procedure for initializing the SCIF is:

1. Set the clock selection in SCSCR2.  
Be sure to clear bits RIE, TIE, and RE to 0.  
When clock output is selected, it is output immediately after SCSCR2 settings are made.
2. Set the data transfer format in SCSMR2.
3. Write a value corresponding to the SCBRR2.  
(Not necessary if an external clock is used.)
4. Wait at least one bit interval, then set the TE bit or RE bit in SCSCR2 to 1. Also set the RIE and TIE bits.  
Setting the TE and RE bits enables the TxD2 and RxD2 pins to be used. When transmitting, the SCIF will go to the mark state; when receiving, it will go to the idle state, waiting for a start bit.

**Figure 16.5 Sample SCIF Initialization Flowchart**

- **Serial data transmission**

Figure 16.6 shows a sample flowchart for serial transmission.

Use the following procedure for serial data transmission after enabling the SCIF for transmission.

**Figure 16.6 Sample Serial Transmission Flowchart**

In serial transmission, the SCIF operates as described below.

1. When data is written into the SCFTDR2, the SCIF transfers the data from SCFTDR2 to the transmit shift register (SCTSR2) and starts transmitting. Confirm that the TDFE flag in SCSSR2 is set to 1 before writing transmit data to SCFTDR2. The number of data bytes that can be written is (16 – transmit trigger setting).
2. When data is transferred from SCFTDR2 to SCTSR2 and transmission is started, consecutive transmit operations are performed until there is no transmit data left in SCFTDR2. When the number of transmit data bytes in SCFTDR2 falls below the transmit trigger number set in the SCFCR2, the TDFE flag is set. If the TIE bit in SCSCR2 is set to 1 at this time, a transmit-FIFO-data-empty interrupt (TXI) request is generated.

The serial transmit data is sent from the TxD2 pin in the following order.

- A. Start bit: One-bit 0 is output.
  - B. Transmit data: 8-bit or 7-bit data is output in LSB-first order.
  - C. Parity bit: One parity bit (even or odd parity) is output. (A format in which a parity bit is not output can also be selected.)
  - D. Stop bit(s): One- or two-bit 1s (stop bits) are output.
  - E. Mark state: 1 is output continuously until the start bit that starts the next transmission is sent.
3. The SCIF checks the SCFTDR2 transmit data at the timing for sending the stop bit. If data is present, the data is transferred from SCFTDR2 to SCTSR2, the stop bit is sent, and then serial transmission of the next frame is started.

If there is no transmit data, the TEND flag in SCSSR2 is set to 1, the stop bit is sent, and then the line goes to the mark state in which 1 is output continuously.

Figure 16.7 shows an example of the operation for transmission.

**Figure 16.7 Example of Transmit Operation  
(Example with 8-Bit Data, Parity, One Stop Bit)**

- When modem control is enabled, transmission can be stopped and restarted in accordance with the  $\overline{\text{CTS2}}$  input value. When  $\overline{\text{CTS2}}$  is set to 1, if transmission is in progress, the line goes to the mark state after transmission of one frame. When  $\overline{\text{CTS2}}$  is set to 0, the next transmit data is output starting from the start bit.

Figure 16.8 shows an example of the operation when modem control is used.

**Figure 16.8 Example of Operation Using Modem Control ( $\overline{\text{CTS2}}$ )**

- **Serial data reception**

Figure 16.9 shows a sample flowchart for serial reception.

Use the following procedure for serial data reception after enabling the SCIF for reception.

**Figure 16.9 Sample Serial Reception Flowchart (1)**

1. Whether a framing error or parity error has occurred in the receive data read from SCFRDR2 can be ascertained from the FER and PER bits in SCSSR2.
2. When a break signal is received, receive data is not transferred to SCFRDR2 while the BRK flag is set. However, note that the last data in SCFRDR2 is H'00 and the break data in which a framing error occurred is stored.

**Figure 16.10 Sample Serial Reception Flowchart (2)**

In serial reception, the SCIF operates as described below.

1. The SCIF monitors the transmission line, and if a 0 start bit is detected, performs internal synchronization and starts reception.
  2. The received data is stored in SCRSR2 in LSB-to-MSB order.
  3. The parity bit and stop bit are received.  
After receiving these bits, the SCIF carries out the following checks.
    - A. Stop bit check: The SCIF checks whether the stop bit is 1. If there are two stop bits, only the first is checked.
    - B. The SCIF checks whether receive data can be transferred from the receive shift register (SCRSR2) to SCFRDR2.
    - C. Break check: The SCIF checks that the BRK flag is 0, indicating that the break state is not set.
 If all the above checks are passed, the receive data is stored in SCFRDR2.
- Note: Reception is not suspended when a receive error occurs.

4. If the RIE bit in SCSCR2 is set to 1 when the RDF or DR flag changes to 1, a receive-FIFO-data-full interrupt (RXI) request is generated.  
If the RIE bit in SCSCR2 is set to 1 when the ER flag changes to 1, a receive-error interrupt (ERI) request is generated.  
If the RIE bit in SCSCR2 is set to 1 when the BRK flag changes to 1, a break reception interrupt (BRI) request is generated.

Figure 16.11 shows an example of the operation for reception.

**Figure 16.11 Example of SCIF Receive Operation  
(Example with 8-Bit Data, Parity, One Stop Bit)**

5. When modem control is enabled, the  $\overline{\text{RTS2}}$  signal is output when SCFRDR2 is empty. When  $\overline{\text{RTS2}}$  is 0, reception is possible. When  $\overline{\text{RTS2}}$  is 1, this indicates that SCFRDR2 is full and reception is not possible.

Figure 16.12 shows an example of the operation when modem control is used.

**Figure 16.12 Example of Operation Using Modem Control ( $\overline{\text{RTS}}$ )**

## 16.4.2 SCIF Interrupts

The SCIF has four interrupt sources: transmit-FIFO-data-empty (TXI), receive-error (ERI), receive-data-full (RXI), and break (BRI).

Table 16.9 shows the interrupt sources and their order of priority. The interrupt sources are enabled or disabled by means of the TIE and RIE bits in SCSSR2. A separate interrupt request is sent to the interrupt controller for each of these interrupt sources.

When the TDFE flag in SCSSR2 is set to 1, a TXI interrupt request is generated. The DMAC can be activated and data transfer performed when this interrupt is generated. The TDFE flag is cleared to 0 when data exceeding the number of transmit triggers is written to SCFTDR2 by the DMAC, the TDFE flag is read as 1, then 0 is written to the TDFE flag.

When the RDF flag in SCSSR2 is set to 1, an RXI interrupt request is generated. The DMAC can be activated and data transfer performed when the RDF flag in SCSSR2 is set to 1. The RDF flag is cleared to 0 when SCFRDR2 is read until the quantity of receive data in SCFRDR2 becomes less than the specified number of receive triggers by the DMAC, the RDF flag is read as 1, then 0 is written to the RDF flag.

When the ER flag in SCSSR2 is set to 1, an ERI interrupt request is generated.

When the BRK flag in SCSSR2 is set to 1, a BRI interrupt request is generated.

The TXI interrupt indicates that transmit data can be written, and the RXI interrupt indicates that there is receive data in SCFRDR2.

**Table 16.9 SCIF Interrupt Sources**

| Interrupt Source | Description                                                                      | DMAC Activation     | Priority on Reset Release |
|------------------|----------------------------------------------------------------------------------|---------------------|---------------------------|
| ERI              | Interrupt initiated by receive error flag (ER)                                   | Not possible        | High<br>↑<br>↓<br>Low     |
| RXI              | Interrupt initiated by receive data FIFO full flag (RDF) or data ready flag (DR) | Possible (RDF only) |                           |
| BRI              | Interrupt initiated by break flag (BRK)                                          | Not possible        |                           |
| TXI              | Interrupt initiated by transmit FIFO data empty flag (TDFE)                      | Possible            |                           |

See section 4, Exception Processing, for priorities and the relationship with non-SCIF interrupts.

## 16.5 Usage Note

Note the following when using the SCIF.

1. **SCFTDR2 Writing and the TDFE Flag:** The TDFE flag in SCSSR2 is set when the number of transmit data bytes written in the SCFTDR2 has fallen below the transmit trigger number set by bits TTRG1 and TTRG0 in the SCFCR2. After TDFE is set, transmit data up to the number of empty bytes in SCFTDR2 can be written, allowing efficient continuous transmission. If the number of data bytes written in SCFTDR2 is equal to or less than the transmit trigger number, the TDFE flag will be set to 1 again after being cleared to 0. TDFE clearing should therefore be carried out after data more than the specified number of transmit triggers has been written to SCFTDR2.  
The number of transmit data bytes in SCFTDR2 can be found from the upper 8 bits of the SCFDR2.
2. **SCFRDR2 Reading and the RDF Flag:** The RDF flag in SCSSR2 is set when the number of receive data bytes in the SCFRDR2 has become equal to or greater than the receive trigger number set by bits RTRG1 and RTRG0 in SCFCR2. After RDF is set, receive data equivalent to the trigger number can be read from SCFRDR2, allowing efficient continuous reception. However, if the number of data bytes in SCFRDR2 is greater than the trigger number, the RDF flag will be set to 1 again even if it is cleared to 0. The RDF flag should therefore be cleared to 0 after being read as 1 after all the receive data has been read.  
The number of receive data bytes in SCFRDR2 can be found from the lower 8 bits of the FIFO data count register (SCFDR2).
3. **Break Detection and Processing:** Break signals can be detected by reading the RxD2 pin directly when a framing error (FER) is detected. In the break state the input from the RxD2 pin consists of all 0s, so the FER flag is set and the parity error flag (PER) may also be set. Note that, although transfer of receive data to SCFRDR2 is halted in the break state, the SCIF receiver continues to operate, so if the BRK flag is cleared to 0 it will be set to 1 again.
4. **Sending a Break Signal:** The I/O condition and level of the TxD2 pin are determined by the SCP2DT bit in SCPDR and bits SCP2MD0 and SCP2MD1 in the SCPCR. This feature can be used to send a break signal.  
To send a break signal during serial transmission, clear the SCP2DT bit to 0 (designating low level), then set the SCP2MD0 and SCP2MD1 bits to 0 and 1, respectively, and finally clear the TE bit to 0 (halting transmission). When the TE bit is cleared to 0, the transmitter is initialized regardless of the current transmission state, and 0 is output from the TxD2 pin.
5. **TEND Flag and TE Bit Processing:** The TEND flag is set to 1 during transmission of the stop bit of the last data. Consequently, if the TE bit is cleared to 0 immediately after setting of the TEND flag has been confirmed, the stop bit will be in the process of transmission and will not be transmitted normally. Therefore, the TE bit should not be cleared to 0 for at least 0.5 serial clock cycles (or 1.5 cycles if two stop bits are used) after setting of the TEND flag setting is confirmed.

6. Receive Data Sampling Timing and Receive Margin: The SCIF operates on a base clock with a frequency of 16 times the transfer rate. In reception, the SCIF synchronizes internally with the fall of the start bit, which it samples on the base clock. Receive data is latched at the rising edge of the eighth base clock pulse. The timing is shown in figure 16.13.

**Figure 16.13 Receive Data Sampling Timing in Asynchronous Mode**

The receive margin in asynchronous mode can therefore be expressed as shown in equation 1.

Equation 1:

$$M = \left| \left( 0.5 - \frac{1}{2N} \right) - (L - 0.5) F - \frac{|D - 0.5|}{N} (1 + F) \right| \times 100\%$$

M: Receive margin (%)

N: Ratio of clock frequency to bit rate (N = 16)

D: Clock duty cycle (D = 0 to 1.0)

L: Frame length (L = 9 to 12)

F: Absolute deviation of clock frequency

From equation 1, if F = 0 and D = 0.5, the receive margin is 46.875%, as given by equation 2.

Equation 2:

When D = 0.5 and F = 0:

$$\begin{aligned} M &= (0.5 - 1/(2 \times 16)) \times 100\% \\ &= 46.875\% \end{aligned}$$

This is a theoretical value. A reasonable margin to allow in system designs is 20% to 30%.

## Section 17 Pin Function Controller

The pin function controller (PFC) is composed of registers for selecting the function of multiplexed pins and the direction of input/output. The pin function and I/O direction can be selected for each pin individually without regard to the operating mode of the LSI. Table 17.1 lists the multiplexed pins.

**Table 17.1 List of Multiplexed Pins**

| <b>Port</b> | <b>Port Function<br/>(Related Module)</b> | <b>Other Function<br/>(Related Module)</b> |
|-------------|-------------------------------------------|--------------------------------------------|
| A           | PTA7 I/O (port)                           | D23 I/O (data bus)                         |
| A           | PTA6 I/O (port)                           | D22 I/O (data bus)                         |

|      | SCPT2 output (port)               | TxD2 output (SCIF)                                       |
| SCPT | SCPT1 I/O (port)                  | SCK0 I/O (SCI)                                           |
| SCPT | SCPT0 input (port)                | RxD0 input (SCI)                                         |
|      | SCPT0 output (port)               | TxD0 output (SCI)                                        |

Notes: SCPT0, and SCPT2 have the same data register to be accessed although they have different input pins and output pins.

## 17.1 Register Description

The pin function controller has the following registers. Refer to section 23, List of Registers, for more details of the addresses and access sizes.

- Port A control register (PACR)
- Port B control register (PBCR)
- Port C control register (PCCR)
- Port D control register (PDCR)
- Port E control register (PECR)
- Port F control register (PFCR)
- Port G control register (PGCR)
- Port H control register (PHCR)
- Port J control register (PJCR)
- SC port control register (SCPCR)

### 17.1.1 Port A Control Register (PACR)

Port A Control Register (PACR) is a 16-bit read/write register that selects the pin functions and the input pull-up MOS control.

| Bit | Bit Name | Initial Value | R/W | Description                                                                                                                     |

### 17.1.2 Port B Control Register (PBCR)

Port B Control Register (PBCR) is a 16-bit read/write register that selects the pin functions and the input pull-up MOS control.

| Bit | Bit Name | Initial Value | R/W | Description                                                                                                                     |
|-----|----------|---------------|-----|---------------------------------------------------------------------------------------------------------------------------------|
| 15  | PB7MD1   | 0             | R/W | PB7 Mode                                                                                                                        |
| 14  | PB7MD0   | 0             | R/W | 00: Other function (See table 17.1)<br>01: Port output<br>10: Port input (Pull-up MOS: on)<br>11: Port input (Pull-up MOS: off) |
| 13  | PB6MD1   | 0             | R/W | PB6 Mode                                                                                                                        |
| 12  | PB6MD0   | 0             | R/W | 00: Other function (See table 17.1)<br>01: Port output<br>10: Port input (Pull-up MOS: on)<br>11: Port input (Pull-up MOS: off) |

| Bit | Bit Name | Initial Value | R/W | Description                                                                                                                     |

### 17.1.6 Port F Control Register (PFCR)

Port F Control Register (PFCR) is a 16-bit read/write register that selects the pin functions and the input pull-up MOS control. PFCR is initialized to H'AAAA (in case of  $\overline{\text{ASEMD0}} = 1$ ) or H'0000 (in case of  $\overline{\text{ASEMD0}} = 0$ ) by power-on resets; however, it is not initialized by manual resets, in standby mode, or in sleep mode.

| Bit | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                      |

### 17.1.7 Port G Control Register (PGCR)

Port G Control Register (PGCR) is a 16-bit read/write register that selects the pin functions and the input pull-up MOS control. PGCR is initialized to H'AAAA (in case of  $\overline{\text{ASEMD0}} = 1$ ) or H'A800 (in case of  $\overline{\text{ASEMD0}} = 0$ ) by power-on resets; however, it is not initialized by manual resets, in standby mode, or in sleep mode.

| Bit | Bit Name | Initial Value | R/W | Description                                                                                                                                       |
|-----|----------|---------------|-----|---------------------------------------------------------------------------------------------------------------------------------------------------|
| 15  | —        | 1             | R   | Reserved                                                                                                                                          |
| 13  | —        | 1             | R   | These bits are always read as 1. The write value should always be 0.                                                                              |
| 14  | —        | 0             | R   | Reserved                                                                                                                                          |
| 12  | —        | 0             | R   | These bits are always read as 0. The write value should always be 0.                                                                              |

### 17.1.9 Port J Control Register (PJCR)

Port J Control Register (PJCR) is a 16-bit read/write register that selects the pin functions.

When D/A output is enabled, port input settings should not be made in PJCR.

When selecting port input, confirm that D/A output is disabled in DACR before making port input settings in PJCR.

| Bit     | Bit Name | Initial Value | R/W | Description                                                                                                  |

### 17.1.10 SC Port Control Register (SCPCR)

SC Port Control Register (SCPCR) is a 16-bit read/write register that selects the pin functions and the input pull-up MOS control. The setting of SCPCR is valid only when the transmit/receive operation is disabled in the setting of the SCSCR register. When the TE bit in SCSCR is set to 1, the other function output state has a higher priority than the SCPCR setting of the TxD2 or TxD0 pin. When the RE bit in SCSCR is set to 1, the input state has a higher priority than the SCPCR setting of the RxD2 or RxD0 pin.

| Bit      | Bit Name | Initial Value | R/W | Description                                                                                                                                       |

When the TE bit is<br>cleared to 0, the TxD0 pin is in the high-impedance<br>state. |

## Section 18 I/O Ports

This LSI has 10 ports (ports A to J and SC). All port pins are multiplexed with other pin functions (Pin Function Controller (PFC) maintains the selection of the pin functions and pull-up MOS control). Each port has a data register which stores the data to the pins.

### 18.1 Port A

Port A is an 8-bit I/O port with the pin configuration shown in figure 18.1. Each pin has an input pull-up MOS, which is controlled by Port A Control Register (PACR) in PFC.

**Figure 18.1 Port A**

#### 18.1.1 Register Description

Port A has the following register. Refer to section 23, List of Registers, for more details of the addresses and access sizes.

- Port A data register (PADR)

#### 18.1.2 Port A Data Register (PADR)

Port A data Register (PADR) is an 8-bit read/write register that stores data for pins PTA7 to PTA0. PA7DT to PA0DT bit corresponds to PTA7 to PTA0 pin. When the pin function is general output port, if the port is read the value of the corresponding PADR bit is returned directly. When the function is general input port, if the port is read the corresponding pin level is read.

| Bit | Bit Name | Initial Value | R/W | Description                            |
|-----|----------|---------------|-----|----------------------------------------|
| 7   | PA7DT    | 0             | R/W | Table 18.1 shows the function of PADR. |
| 6   | PA6DT    | 0             | R/W |                                        |
| 5   | PA5DT    | 0             | R/W |                                        |
| 4   | PA4DT    | 0             | R/W |                                        |
| 3   | PA3DT    | 0             | R/W |                                        |
| 2   | PA2DT    | 0             | R/W |                                        |
| 1   | PA1DT    | 0             | R/W |                                        |
| 0   | PA0DT    | 0             | R/W |                                        |

**Table 18.1 Read/Write Operation of the Port A Data Register (PADR)**

| PAnMD1 | PAnMD0 | Pin State               | Read       | Write                                                    |
|--------|--------|-------------------------|------------|----------------------------------------------------------|
| 0      | 0      | Other function          | PADR value | Value is written to PADR, but does not affect pin state. |
|        | 1      | Output                  | PADR value | Write value is output from pin.                          |
| 1      | 0      | Input (Pull-up MOS on)  | Pin state  | Value is written to PADR, but does not affect pin state. |
|        | 1      | Input (Pull-up MOS off) | Pin state  | Value is written to PADR, but does not affect pin state. |

(n = 0 to 7)

## 18.2 Port B

Port B is an 8-bit I/O port with the pin configuration shown in figure 18.2. Each pin has an input pull-up MOS, which is controlled by Port B Control Register (PBCR) in PFC.

**Figure 18.2 Port B**

### 18.2.1 Register Description

Port B has the following register. Refer to section 23, List of Registers, for more details of the addresses and access size.

- Port B data register (PBDR)

### 18.2.2 Port B Data Register (PBDR)

Port B data register (PBDR) is an 8-bit read/write register that stores data for pins PTB7 to PTB0. PB7DT to PB0DT bit corresponds to PTB7 to PTB0 pin. When the pin function is general output port, if the port is read the value of the corresponding PBDR bit is returned directly. When the function is general input port, if the port is read the corresponding pin level is read.

| Bit | Bit Name | Initial Value | R/W | Description                            |
|-----|----------|---------------|-----|----------------------------------------|
| 7   | PB7DT    | 0             | R/W | Table 18.2 shows the function of PBDR. |
| 6   | PB6DT    | 0             | R/W |                                        |
| 5   | PB5DT    | 0             | R/W |                                        |
| 4   | PB4DT    | 0             | R/W |                                        |
| 3   | PB3DT    | 0             | R/W |                                        |
| 2   | PB2DT    | 0             | R/W |                                        |
| 1   | PB1DT    | 0             | R/W |                                        |
| 0   | PB0DT    | 0             | R/W |                                        |

**Table 18.2 Read/Write Operation of the Port B Data Register (PBDR)**

| PBnMD1 | PBnMD0 | Pin State               | Read       | Write                                                    |
|--------|--------|-------------------------|------------|----------------------------------------------------------|
| 0      | 0      | Other function          | PBDR value | Value is written to PBDR, but does not affect pin state. |
|        | 1      | Output                  | PBDR value | Write value is output from pin.                          |
| 1      | 0      | Input (Pull-up MOS on)  | Pin state  | Value is written to PBDR, but does not affect pin state. |
|        | 1      | Input (Pull-up MOS off) | Pin state  | Value is written to PBDR, but does not affect pin state. |

(n = 0 to 7)

## 18.3 Port C

Port C is an 8-bit I/O port with the pin configuration shown in figure 18.3. Each pin has an input pull-up MOS, which is controlled by Port C Control Register (PCCR) in PFC.

**Figure 18.3 Port C**

### 18.3.1 Register Description

Port C has the following register. Refer to section 23, List of Registers, for more details of the addresses and access sizes.

- Port C data register (PCDR)

### 18.3.2 Port C Data Register (PCDR)

Port C data register (PCDR) is an 8-bit read/write register that stores data for pins PTC7 to PTC0. PC7DT to PC0DT bit corresponds to PTC7 to PTC0 pin. When the pin function is general output port, if the port is read, the value of the corresponding PCDR bit is returned directly. When the function is general input port, if the port is read, the corresponding pin level is read. Table 18.3 shows the function of PCDR.

PCDR is initialized to H'00 by a power-on reset. It retains its previous value in standby mode and sleep mode, and in a manual reset.

| Bit | Bit Name | Initial Value | R/W | Description                            |
|-----|----------|---------------|-----|----------------------------------------|
| 7   | PC7DT    | 0             | R/W | Table 18.3 shows the function of PCDR. |
| 6   | PC6DT    | 0             | R/W |                                        |
| 5   | PC5DT    | 0             | R/W |                                        |
| 4   | PC4DT    | 0             | R/W |                                        |
| 3   | PC3DT    | 0             | R/W |                                        |
| 2   | PC2DT    | 0             | R/W |                                        |
| 1   | PC1DT    | 0             | R/W |                                        |
| 0   | PC0DT    | 0             | R/W |                                        |

**Table 18.3 Read/Write Operation of the Port C Data Register (PCDR)**

| PCnMD1 | PCnMD0 | Pin State                | Read       | Write                                                    |
|--------|--------|--------------------------|------------|----------------------------------------------------------|
| 0      | 0      | Other function           | PCDR value | Value is written to PCDR, but does not affect pin state. |
|        | 1      | Output                   | PCDR value | Write value is output from pin.                          |
| 1      | 0      | Input (Pull-up MOS: on)  | Pin state  | Value is written to PCDR, but does not affect pin state. |
|        | 1      | Input (Pull-up MOS: off) | Pin state  | Value is written to PCDR, but does not affect pin state. |

(n = 0 to 7)

## 18.4 Port D

Port D is an 8-bit I/O port with the pin configuration shown in figure 18.4. Each pin has an input pull-up MOS, which is controlled by Port D Control Register (PDCR) in PFC.

**Figure 18.4 Port D**

## 18.4.1 Register Description

Port D has the following register. Refer to section 23, List of Registers, for more details of the addresses and access sizes.

- Port D data register (PDDR)

## 18.4.2 Port D Data Register (PDDR)

Port D data register (PDDR) is an 8-bit read/write register that stores data for pins PTD7 to PTD0. PD7DT to PD0DT bit corresponds to PTD7 to PTD0 pin. When the pin function is general output port, if the port is read, the value of the corresponding PDDR bit is returned directly. When the function is general input port, if the port is read, the corresponding pin level is read.

PDDR is initialized to H'00 by a power-on reset. It retains its previous value in standby mode and sleep mode, and in a manual reset.

| Bit | Bit Name | Initial Value | R/W | Description                            |
|-----|----------|---------------|-----|----------------------------------------|
| 7   | PD7DT    | 0             | R/W | Table 18.4 shows the function of PDDR. |
| 6   | PD6DT    | 0             | R/W |                                        |
| 5   | PD5DT    | 0             | R/W |                                        |
| 4   | PD4DT    | 0             | R/W |                                        |
| 3   | PD3DT    | 0             | R/W |                                        |
| 2   | PD2DT    | 0             | R/W |                                        |
| 1   | PD1DT    | 0             | R/W |                                        |
| 0   | PD0DT    | 0             | R/W |                                        |

**Table 18.4 Read/Write Operation of the Port D Data Register (PDDR)**

| PDnMD1 | PDnMD0 | Pin State                | Read       | Write                                                    |
|--------|--------|--------------------------|------------|----------------------------------------------------------|
| 0      | 0      | Other function           | PDDR value | Value is written to PDDR, but does not affect pin state. |
|        | 1      | Output                   | PDDR value | Write value is output from pin.                          |
| 1      | 0      | Input (Pull-up MOS: on)  | Pin state  | Value is written to PDDR, but does not affect pin state. |
|        | 1      | Input (Pull-up MOS: off) | Pin state  | Value is written to PDDR, but does not affect pin state. |

(n = 0 to 7)

## 18.5 Port E

Port E is an 8-bit I/O port with the pin configuration shown in figure 18.5. Each pin has an input pull-up MOS, which is controlled by Port E Control Register (PECR) in PFC.

**Figure 18.5 Port E**

### 18.5.1 Register Description

Port E has the following register. Refer to section 23, List of Registers, for more details of the addresses and access sizes.

- Port E data register (PEDR)

### 18.5.2 Port E Data Register (PEDR)

Port E data register (PEDR) is an 8-bit read/write register that stores data for pins PTE7 to PTE0. PE7DT to PE0DT bit corresponds to PTE7 to PTE0 pin. When the pin function is general output port, if the port is read the value of the corresponding PEDR bit is returned directly. When the function is general input port, if the port is read the corresponding pin level is read.

PEDR is initialized to H'00 by a power-on reset. It retains its previous value in standby mode and sleep mode, and in a manual reset.

| Bit | Bit Name | Initial Value | R/W | Description                            |
|-----|----------|---------------|-----|----------------------------------------|
| 7   | PE7DT    | 0             | R/W | Table 18.5 shows the function of PEDR. |
| 6   | PE6DT    | 0             | R/W |                                        |
| 5   | PE5DT    | 0             | R/W |                                        |
| 4   | PE4DT    | 0             | R/W |                                        |
| 3   | PE3DT    | 0             | R/W |                                        |
| 2   | PE2DT    | 0             | R/W |                                        |
| 1   | PE1DT    | 0             | R/W |                                        |
| 0   | PE0DT    | 0             | R/W |                                        |

**Table 18.5 Read/Write Operation of the Port E Data Register (PEDR)**

| PEnMD1 | PEnMD0 | Pin State                | Read       | Write                                                    |
|--------|--------|--------------------------|------------|----------------------------------------------------------|
| 0      | 0      | Other function           | PEDR value | Value is written to PEDR, but does not affect pin state. |
|        | 1      | Output                   | PEDR value | Write value is output from pin.                          |
| 1      | 0      | Input (Pull-up MOS: on)  | Pin state  | Value is written to PEDR, but does not affect pin state. |
|        | 1      | Input (Pull-up MOS: off) | Pin state  | Value is written to PEDR, but does not affect pin state. |

(n = 0 to 7)

## 18.6 Port F

Port F is a 7-bit input/output port with the pin configuration shown in figure 18.6. Each pin has an input pull-up MOS, which is controlled by Port F Control Register (PFCR) in PFC.

**Figure 18.6 Port F**

## 18.6.1 Register Description

Port F has the following register. Refer to section 23, List of Registers, for more details of the addresses and access sizes.

- Port F data register (PFDR)

## 18.6.2 Port F Data Register (PFDR)

Port F data register (PFDR) is an 8-bit register composed of a 1-bit readable register and a 7-bit readable/writable register. This register stores data for pins PTF6 to PTF0. PF6DT to PF0DT bit corresponds to PTF6 to PTF0 pin. When the function is general input port, if the port is read the corresponding pin level is read.

PFDR is initialized by a power-on reset, after which the general input port function (pull-up MOS on) is set as the initial pin function, and the corresponding pin levels are read. It retains its previous value in standby mode and sleep mode, and in a manual reset.

| Bit | Bit Name | Initial Value | R/W | Description                            |
|-----|----------|---------------|-----|----------------------------------------|
| 7   | —        | 0             | R   | Reserved                               |
| 6   | PF6DT    | 0             | R/W | Table 18.6 shows the function of PFDR. |
| 5   | PF5DT    | 0             | R/W |                                        |
| 4   | PF4DT    | 0             | R/W |                                        |
| 3   | PF3DT    | 0             | R/W |                                        |
| 2   | PF2DT    | 0             | R/W |                                        |
| 1   | PF1DT    | 0             | R/W |                                        |
| 0   | PF0DT    | 0             | R/W |                                        |

**Table 18.6 Read/Write Operation of the Port F Data Register (PFDR)**

| PFnMD1 | PFnMD0 | Pin State                | Read       | Write                                                     |
|--------|--------|--------------------------|------------|-----------------------------------------------------------|
| 0      | 0      | Other functions          | PFDR value | Can be written to PFDR but does not affect the pin state. |
|        | 1      | Output                   | PFDR value | A value to be written is output from the pin.             |
| 1      | 0      | Input (Pull-up MOS: on)  | Pin state  | Can be written to PFDR but does not affect the pin state. |
|        | 1      | Input (Pull-up MOS: off) | Pin state  | Can be written to PFDR but does not affect the pin state. |

(n = 0 to 6)

## 18.7 Port G

Port G is a 6-bit input port with the pin configuration shown in figure 18.7. Each pin has an input pull-up MOS, which is controlled by Port G Control Register (PGCR) in PFC.

**Figure 18.7 Port G**

### 18.7.1 Register Description

Port G has the following register. Refer to section 23, List of Registers, for more details of the addresses and access sizes.

- Port G data register (PGDR)

### 18.7.2 Port G Data Register (PGDR)

Port G data register (PGDR) is an 8-bit read register that stores data for pins PTG5 to PTG0. PG5DT to PG0DT bit corresponds to PTG5 to PTG0 pin. When the function is general input port, if the port is read the corresponding pin level is read.

PGDR is initialized by a power-on reset, after which the general input port function (pull-up MOS on) is set as the initial pin function, and the corresponding pin levels are read. It retains its previous value in standby mode and sleep mode, and in a manual reset.

| Bit | Bit Name | Initial Value | R/W | Description                            |
|-----|----------|---------------|-----|----------------------------------------|
| 7   | —        | *             | R   | Reserved                               |
| 6   | —        | *             | R   |                                        |
| 5   | PG5DT    | *             | R   | Table 18.7 shows the function of PGDR. |
| 4   | PG4DT    | *             | R   |                                        |
| 3   | PG3DT    | *             | R   |                                        |
| 2   | PG2DT    | *             | R   |                                        |
| 1   | PG1DT    | *             | R   |                                        |
| 0   | PG0DT    | *             | R   |                                        |

Note: \* Undefined

**Table 18.7 Read/Write Operation of the Port G Data Register (PGDR)**

| PGnMD1 | PGnMD0 | Pin State                | Read      | Write                            |
|--------|--------|--------------------------|-----------|----------------------------------|
| 0      | 0      | Other function           | Low level | Ignored (no affect on pin state) |
|        | 1      | Reserved                 | —         | Ignored (no affect on pin state) |
| 1      | 0      | Input (Pull-up MOS: on)  | Pin state | Ignored (no affect on pin state) |
|        | 1      | Input (Pull-up MOS: off) | Pin state | Ignored (no affect on pin state) |

(n = 0 to 5)

## 18.8 Port H

Port H is a 7-bit I/O and port with the pin configuration shown in figure 18.8. Each pin has an input pull-up MOS, which is controlled by Port H Control Register (PHCR) in PFC.

**Figure 18.8 Port H**

### 18.8.1 Register Description

Port H has the following register. Refer to section 23, List of Registers, for more details of the addresses and access sizes.

- Port H data register (PHDR)

### 18.8.2 Port H Data Register (PHDR)

Port H data register (PHDR) is a 7-bit read/write and 1-bit read register that stores data for pins PTH6 to PTH0. PH6DT to PH0DT bit corresponds to PTH6 to PTH0 pin. When the pin function is general output port, if the port is read, the value of the corresponding PHDR bit is returned directly. When the function is general input port, if the port is read, the corresponding pin level is read.

PHDR is initialized to H'00 by a power-on reset. It retains its previous value in standby mode and sleep mode, and in a manual reset.

Note that the low level is read if bits 6 to 0 are read except in general-purpose input.

| Bit | Bit Name | Initial Value | R/W | Description                            |
|-----|----------|---------------|-----|----------------------------------------|
| 7   | —        | *             | R   | Reserved                               |

| PHnMD1 | PHnMD0 | Pin State                | Read       | Write                                                    |
|--------|--------|--------------------------|------------|----------------------------------------------------------|
| 0      | 0      | Other function           | PHDR value | Value is written to PHDR, but does not affect pin state. |
|        | 1      | Output                   | PHDR value | Write value is output from pin.                          |
| 1      | 0      | Input (Pull-up MOS: on)  | Pin state  | Value is written to PHDR, but does not affect pin state. |
|        | 1      | Input (Pull-up MOS: off) | Pin state  | Value is written to PHDR, but does not affect pin state. |

(n = 0 to 6)

## 18.9 Port J

Port J is a 4-bit input port with the pin configuration shown in figure 18.9.

**Figure 18.9 Port J**

### 18.9.1 Register Description

Port J has the following register. Refer to section 23, List of Registers, for more details of the addresses and access sizes.

- Port J data register (PJDR)

## 18.9.2 Port J Data Register (PJDR)

Port J data register (PJDR) is an 8-bit read register that stores data for pins PTJ7 to PTJ0. PJ3DT to PJ0DT bit corresponds to PTJ3 to PTJ0 pin. When the pin function is general output port, if the port is read the value of the corresponding PJDR bit is returned directly. When the function is general input port, if the port is read, the corresponding pin level is read.

| Bit | Bit Name | Initial Value | R/W | Description                            |
|-----|----------|---------------|-----|----------------------------------------|
| 7   | —        | 0             | R   | Reserved                               |
| 6   | —        | 0             | R   |                                        |
| 5   | —        | 0             | R   |                                        |
| 4   | —        | 0             | R   |                                        |

| 2   | PJ2DT    | 0             | R   |                                        |
| 1   | PJ1DT    | 0             | R   |                                        |
| 0   | PJ0DT    | 0             | R   |                                        |

**Table 18.9 Read/Write Operation of the Port J Data Register (PJDR)**

| PJnMD1 | PJnMD0 | Pin State                        | Read      | Write                            |
|--------|--------|----------------------------------|-----------|----------------------------------|
| 0      | 0      | Other function                   | Low level | Ignored (no affect on pin state) |
|        | 1      | Reserved<br>(Setting prohibited) |           | Ignored (no affect on pin state) |
| 1      | 0      | Input                            | Pin state | Ignored (no affect on pin state) |
|        | 1      | Input                            | Pin state | Ignored (no affect on pin state) |

(n = 0 to 3)

## 18.10 SC Port

SC port is a 3-bit I/O, 2-bit output and 4-bit input port with the pin configuration shown in figure 18.10. Each pin has an input pull-up MOS, which is controlled by SC port Control Register (SCPCR) in PFC.

Figure 18.10 SC Port

### 18.10.1 Register Description

Port SC has the following register. Refer to section 23, List of Registers, for more details of the addresses and access sizes.

- SC Port data register (SCPDR)

### 18.10.2 Port SC Data Register (SCPDR)

Port SC data register (SCPDR) is a 5-bit read/write and 3-bit read register that stores data for pins SCPT5 to SCPT0. SCP5DT to SCP0DT bit corresponds to SCPT5 to SCPT0 pin. When the pin function is general output port, if the port is read, the value of the corresponding SCPDR bit is returned directly. When the function is general input port, if the port is read, the corresponding pin level is read.

SCPDR is initialized to B'\*\*\*00000 by a power-on reset. After initialization, the general input port function (pull-up MOS on) is set as the initial pin function, and the corresponding pin levels are read from bits SCP5DT to SCP3DT and SCP1DT. SCPDR retains its previous value in standby mode and sleep mode, and in a manual reset.

Note that the low level is read if bit 7 is read except in general-purpose input.

When reading the state of the RxD2 and RxD0 pins of the SCP2DT and SCP0DT bits in SCPDR without clearing the TE or RE bit in SCSCR to 0, set the RE bit in SCSCR to 1. When the RE bit is set to 1, the RxD pin is for input and the pin state can be read before the setting of SCPCR.

| Bit | Bit Name | Initial Value | R/W | Description                             |
|-----|----------|---------------|-----|-----------------------------------------|
| 7   | —        | *             | R   | Reserved                                |
| 6   | —        | *             | R   |                                         |
| 5   | SCP5DT   | *             | R   | Table 18.10 shows the function of SCPDR |
| 4   | SCP4DT   | 0             | R/W |                                         |
| 3   | SCP3DT   | 0             | R/W |                                         |
| 2   | SCP2DT   | 0             | R/W |                                         |
| 1   | SCP1DT   | 0             | R/W |                                         |
| 0   | SCP0DT   | 0             | R/W |                                         |

Note: \* Undefined

|         | 1       | Reserved<br>(Setting prohibited) | —         | Ignored (no affect on pin state) |
| 1       | 0       | Input (Pull-up MOS: on)          | Pin state | Ignored (no affect on pin state) |
|         | 1       | Input (Pull-up MOS: off)         | Pin state | Ignored (no affect on pin state) |

(n = 5)

## Section 19 A/D Converter (ADC)

This LSI includes a 10-bit successive-approximation A/D converter with a selection of up to four analog input channels. Figure 19.1 shows the block diagram of the A/D converter.

### 19.1 Features

A/D converter features are listed below.

- 10-bit resolution
- 4 input channels
- High-speed conversion
  - Conversion time: minimum 15  $\mu$ s per channel (with  $P\phi = 33$ -MHz peripheral clock)
- Three conversion modes
  - Single mode: A/D conversion of one channel
  - Multi mode: A/D conversion on one to four channels
  - Scan mode: Continuous A/D conversion on one to four channels
- Four 16-bit data registers
  - A/D conversion results are transferred for storage into data registers corresponding to the channels.
- Sample-and-hold function
- A/D conversion can be externally triggered
- A/D interrupt requested at the end of conversion
  - At the end of A/D conversion, an A/D end interrupt (ADI) can be requested.

Legend:

ADCR: A/D control register  
 ADCSR: A/D control/status register  
 ADDRA: A/D data register A  
 ADDRb: A/D data register B  
 ADDRc: A/D data register C  
 ADDRd: A/D data register D

**Figure 19.1 A/D Converter Block Diagram**

## 19.2 Input/Output Pin

Table 19.1 summarizes the A/D converter's input pins.  $AV_{CC}$  and  $AV_{SS}$  are the power supply for the analog circuits in the A/D converter.  $AV_{CC}$  also functions as the A/D converter reference voltage.

**Table 19.1 A/D Converter Pins**

| Pin Name                       | Abbreviation       | I/O   | Function                                           |
|--------------------------------|--------------------|-------|----------------------------------------------------|
| Analog power-supply pin        | $AV_{CC}$          | Input | Analog power supply                                |
| Analog ground pin              | $AV_{SS}$          | Input | Analog ground and reference voltage                |
| Analog input pin 0             | AN0                | Input | Group 0 analog inputs                              |
| Analog input pin 1             | AN1                | Input |                                                    |
| Analog input pin 2             | AN2                | Input |                                                    |
| Analog input pin 3             | AN3                | Input |                                                    |
| A/D external trigger input pin | $\overline{ADTRG}$ | Input | External trigger input for starting A/D conversion |

## 19.3 Register Description

The A/D converter has the following registers. Refer to section 23, List of Registers, for more details of the addresses and access sizes.

- A/D data register A (ADDRAH)  
The upper and lower bytes of ADDRA may be represented by ADDRAH and ADDRAL, respectively.
- A/D data register B (ADDRBH)  
The upper and lower bytes of ADDR B may be represented by ADDR BH and ADDRBL, respectively.
- A/D data register C (ADDRCH)  
The upper and lower bytes of ADDR C may be represented by ADDRCH and ADDRCL, respectively.
- A/D data register D (ADDRDH)  
The upper and lower bytes of ADDR D may be represented by ADDR DH and ADDRDL, respectively.
- A/D control/status register (ADCSR)
- A/D control register (ADCR)

### 19.3.1 A/D Data Registers A–D (ADDRA–ADDRD)

The four A/D data registers (ADDRA–ADDRD) are 16-bit read-only registers that store the results of A/D conversion.

An A/D conversion produces 10-bit data, which is transferred for storage into the A/D data register corresponding to the selected channel. The upper 8 bits of the result are stored in the upper byte (bits 15 to 8) of the A/D data register. The lower 2 bits are stored in the lower byte (bits 7 and 6). Bits 5 to 0 of an A/D data register are reserved bits that always read 0. For the reading of the data, see section 19.4, Bus Master Interface, and section 19.9.3, Access size and Read Data. Table 19.2 indicates the pairings of analog input channels and A/D data registers.

| Bit     | Bit Name   | Initial Value | R/W | Description                      |
|---------|------------|---------------|-----|----------------------------------|
| 15 to 6 | AD9 to AD0 | 0             | R   | Bit data (10 bits)               |
| 5 to 0  | —          | 0             | R   | Reserved                         |
|         |            |               |     | These bits are always read as 0. |

**Table 19.2 Analog Input Channels and A/D Data Registers**

| Analog Input Channel |                   |
|----------------------|-------------------|
| Group 0              | A/D Data Register |
| AN0                  | ADDRA             |
| AN1                  | ADDRB             |
| AN2                  | ADDRC             |
| AN3                  | ADDRD             |

### 19.3.2 A/D Control/Status Register (ADCSR)

ADCSR is an 8-bit read/write register that selects the mode and controls the A/D converter.

| Bit | Bit Name | Initial Value | R/W    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----|----------|---------------|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

Note: \* Only can be written to clear the flag.

### 19.3.3 A/D Control Register (ADCR)

ADCR is an 8-bit read/write register that enables or disables external triggering of A/D conversion. ADCR is initialized to H'07 by a reset and in standby mode.

| Bit | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                                                                                                                                                   |

## 19.4 Bus Master Interface

ADDRA to ADDR1D are 16-bit registers, but they are connected to the bus master by the upper 8 bits of the 16-bit peripheral data bus. Therefore, although the upper byte can be accessed directly by the bus master, the lower byte is read through an 8-bit temporary register (TEMP).

An A/D data register is read as follows. When the upper byte is read, the upper-byte value is transferred directly to the bus master and the lower-byte value is transferred into TEMP. Next, when the lower byte is read, the TEMP contents are transferred to the bus master.

When reading an A/D data register, always read the upper byte before the lower byte. It is possible to read only the upper byte, but if only the lower byte is read, the read value is not guaranteed.

Figure 19.2 shows the data flow for access to an A/D data register.

**Figure 19.2 A/D Data Register Access Operation (Reading H'AA40)**

# 19.5 Access Size of A/D Data Register

## 19.5.1 Word Access

When A/D data registers (ADDRA to ADDR D) are read in word, A/D data register values are read from bits 15 to 8, and invalid data is read from bits 7 to 0.

Figure 19.3 shows an example of reading ADDR AH.

Figure 19.3 Word Access Example

## 19.5.2 Longword Access

When A/D data registers are read in longword, the upper byte of the A/D data register is read from bits 31 to 24, invalid data from bits 23 to 16, the lower byte of the A/D data register from bits 15 to 8, and invalid data from bits 7 to 0.

Figure 19.4 shows an example of reading ADDR AH.

Figure 19.4 Longword Access Example

# 19.6 Operation

The A/D converter operates by successive approximations with 10-bit resolution. It has two operating modes: single mode and scan mode.

## 19.6.1 Single Mode (MULTI = 0)

Single mode should be selected when only one A/D conversion on one channel is required. A/D conversion starts when the ADST bit in ADCSR is set to 1 by software, or by external trigger input. The ADST bit remains set to 1 during A/D conversion and is automatically cleared to 0 when conversion ends.

When conversion ends the ADF bit is set to 1. If the ADIE bit is also set to 1, an ADI interrupt is requested at this time. To clear the ADF flag to 0, first read ADCSR, then write 0 in ADF.

When the mode or analog input channel must be switched during A/D conversion, to prevent incorrect operation, first clear the ADST bit to 0 in ADCSR to halt A/D conversion. After making the necessary changes, set the ADST bit to 1 to start A/D conversion again. The ADST bit can be set at the same time as the mode or channel is changed.

Typical operations when channel 1 (AN1) is selected in single mode are described next.

Figure 19.5 shows a timing diagram for this example.

1. Single mode is selected ( $MULTI = 0$ ), input channel AN1 is selected ( $CH2 = CH1 = 0, CH0 = 1$ ), the A/D interrupt is enabled ( $ADIE = 1$ ), and A/D conversion is started ( $ADST = 1$ ).
2. When A/D conversion is completed, the result is transferred into ADDR<sub>B</sub>. At the same time the ADF flag is set to 1, the ADST bit is cleared to 0, and the A/D converter becomes idle.
3. Since  $ADF = 1$  and  $ADIE = 1$ , an ADI interrupt is requested.
4. The A/D interrupt processing routine starts.
5. The routine reads ADCSR, then writes 0 in the ADF flag.
6. The routine reads and processes the conversion result ( $ADDRB = 0$ ).
7. Execution of the A/D interrupt processing routine ends. Then, when the ADST bit is set to 1, A/D conversion starts to execute 2 to 7 above.

**Figure 19.5 Example of A/D Converter Operation (Single Mode, Channel 1 Selected)**

## 19.6.2 Multi Mode (MULTI = 1, SCN = 0)

Multi mode should be selected when performing multi channel A/D conversions on one or more channels. When the ADST bit in ADCSR is set to 1 by software or external trigger input, A/D conversion starts on the first channel in the group (AN0 when CH2 = 0). When two or more channels are selected, after conversion of the first channel ends, conversion of the second channel (AN1) starts immediately. When A/D conversions end on the selected channels, the ADST bit is cleared to 0. The conversion results are transferred for storage into the A/D data registers corresponding to the channels.

When the mode or analog input channel selection must be changed during A/D conversion, to prevent incorrect operation, first clear the ADST bit to 0 in ADCSR to halt A/D conversion. After making the necessary changes, set the ADST bit to 1. A/D conversion will start again from the first channel in the group. The ADST bit can be set at the same time as the mode or channel selection is changed.

Typical operations when three channels in group 0 (AN0 to AN2) are selected in scan mode are described next. Figure 19.6 shows a timing diagram for this example.

1. Multi mode is selected (MULTI = 1, SCN = 0), channel group 0 is selected (CH2 = 0), analog input channels AN0 to AN2 are selected (CH1 = 1, CH0 = 0), and A/D conversion is started (ADST = 1).
2. When A/D conversion of the first channel (AN0) is completed, the result is transferred into ADDRA. Next, conversion of the second channel (AN1) starts automatically.
3. Conversion proceeds in the same way through the third channel (AN2).
4. When conversion of all selected channels (AN0 to AN2) is completed, the ADF flag is set to 1 and ADST bit is cleared to 0. If the ADIE bit is set to 1, an ADI interrupt is requested at this time.

When the ADST bit is cleared to 0, A/D conversion stops. After that, if the ADST bit is set to 1, A/D conversion starts again from the first channel (AN0).

**Figure 19.6 Example of A/D Converter Operation (Multi Mode, Channels AN0 to AN2 Selected)**

### 19.6.3 Scan Mode (MULTI = 1, SCN = 1)

Scan mode is useful for monitoring analog inputs in a group of one or more channels. When the ADST bit in the ADCSR is set to 1 by software or external trigger input, A/D conversion starts on the first channel in the group (AN0 when CH2 = 0). When two or more channels are selected, after conversion of the first channel ends, conversion of the second channel (AN1) starts immediately. A/D conversion continues cyclically on the selected channels until the ADST bit is cleared to 0. The conversion results are transferred for storage into the ADDRA to ADDR D corresponding to the channels.

When the mode or analog input channel must be changed during analog conversion, to prevent incorrect operation, first clear the ADST bit to 0 to halt A/D conversion. After making the necessary changes, set the ADST bit to 1. A/D conversion will start again from the first channel in the group. The ADST bit can be set at the same time as the mode or channel selection is changed.

Typical operations when three channels (AN0 to AN2) are selected in scan mode are described next. Figure 19.7 shows a timing diagram for this example.

## 19.6.4 Input Sampling and A/D Conversion Time

The A/D converter has a built-in sample-and-hold circuit. The A/D converter samples the analog input at a time  $t_D$  after the ADST bit in ADCSR is set to 1, then starts conversion. Figure 19.5 shows the A/D conversion timing. Table 19.3 indicates the A/D conversion time.

As indicated in figure 19.8, the A/D conversion time includes  $t_D$  and the input sampling time. The length of  $t_D$  varies depending on the timing of the write access to ADCSR. The total conversion time therefore varies within the ranges indicated in table 19.3.

In multi mode and scan mode, the values given in table 19.3 apply to the first conversion. In the second and subsequent conversions the conversion time is fixed at 512 states when CKS = 0 or 256 states when CKS = 1.

In any cases, the conversion time should be set in the range as shown in table 24.12 of section 24, Electrical Characteristics, by setting the CKS bit in ADCSR according to the  $P\phi$  frequency.

Figure 19.8 A/D Conversion Timing

**Table 19.3 A/D Conversion Time (Single Mode)**

|                            | Symbol     | CKS = 0 |     |     | CKS = 1 |     |     |
|----------------------------|------------|---------|-----|-----|---------|-----|-----|
|                            |            | Min     | Typ | Max | Min     | Typ | Max |
| A/D conversion start delay | $t_d$      | 17      | —   | 28  | 10      | —   | 17  |
| Input sampling time        | $t_{SPL}$  | —       | 129 | —   | —       | 65  | —   |
| A/D conversion time        | $t_{CONV}$ | 514     | —   | 525 | 259     | —   | 266 |

Note: Values in the table are numbers of states ( $t_{cyc}$ ).

### 19.6.5 External Trigger Input Timing

A/D conversion can be externally triggered. When the TRGE1, TRGE0 bits in ADCR are set to 1, external trigger input is enabled at the  $\overline{ADTRG}$  pin. A high-to-low transition at the  $\overline{ADTRG}$  pin sets the ADST bit in ADCSR to 1, starting A/D conversion. Other operations, regardless of the conversion mode, are the same as if the ADST bit had been set to 1 by software. Figure 19.9 shows the timing.

**Figure 19.9 External Trigger Input Timing**

## 19.7 Interrupt Requests

The A/D converter generates an interrupt (ADI) at the end of A/D conversion. The ADI interrupt request can be enabled or disabled by the ADIE bit in ADCSR.

## 19.8 Definitions of A/D Conversion Accuracy

The A/D converter compares an analog value input from an analog input channel to its analog reference value and converts it into 10-bit digital data. The absolute accuracy of this A/D conversion is the deviation between the input analog value and the output digital value. It includes the following errors:

- Offset error
- Full-scale error
- Quantization error
- Nonlinearity error

These four error quantities are explained below using figure 19.10. In the figure, the 10 bits of the A/D converter have been simplified to 3 bits.

Offset error is the deviation between actual and ideal A/D conversion characteristics when the digital output value changes from the minimum (zero voltage) 0000000000 (000 in the figure) to 0000000001 (001 in the figure) (figure 19.10, item (1)). Full-scale error is the deviation between actual and ideal A/D conversion characteristics when the digital output value changes from the 1111111110 (110 in the figure) to the maximum 1111111111 (111 in the figure) (figure 19.10, item (2)). Quantization error is the intrinsic error of the A/D converter and is expressed as 1/2 LSB (figure 19.10, item (3)). Nonlinearity error is the deviation between actual and ideal A/D conversion characteristics between zero voltage and full-scale voltage (figure 19.10, item (4)). Note that it does not include offset, full-scale or quantization error.

**Figure 19.10 Definitions of A/D Conversion Accuracy**

## 19.9 Usage Note

When using the A/D converter, note the points listed in section 19.7.1 below.

### 19.9.1 Setting Analog Input Voltage

- Analog Input Voltage Range: During A/D conversion, the voltages input to the analog input pins ANn should be in the range  $AV_{SS} \leq ANn \leq AV_{CC}$  ( $n = 0$  to  $3$ ).
- Relationships of  $AV_{CC}$  and  $AV_{SS}$  to  $V_{CC}$  and  $V_{SS}$ :  $AV_{CC}$ ,  $AV_{SS}$ ,  $V_{CC}$  and  $V_{SS}$  should be related as follows:  $AV_{CC} = V_{CC} \pm 0.2 \text{ V}$  and  $AV_{SS} = V_{SS}$ .

### 19.9.2 Processing of Analog Input Pins

To prevent damage from voltage surges at the analog input pins (AN0 to AN3), connect an input protection circuit like the one shown in figure 19.11. The circuit shown also includes an RC filter to suppress noise. This circuit is shown as an example; The circuit constants should be selected according to actual application conditions. Table 19.4 lists the analog input pin specifications and figure 19.12 shows an equivalent circuit diagram of the analog input ports.

### 19.9.3 Access Size and Read Data

Table 19.5 shows the relationship between access size and read data. Note the read data obtained with different access sizes, bus widths, and endian modes.

The case is shown here in which H'3FF is obtained when  $AV_{CC}$  is input as an analog input. FF is the data containing the upper 8 bits of the conversion result, and C0 is the data containing the lower 2 bits.

Figure 19.11 Example of Analog Input Protection Circuit

| Word access     | MOV . L | #ADDRAH, R9 |                  |          |                  |          |                |          |
|                 | MOV . W | @R9, R8     | FFxxFFxx         | FFxxFFxx | FFxx             | FFxx     | FFxx           | xxFF     |
|                 | MOV . L | #ADDRAL, R9 |                  |          |                  |          |                |          |
|                 | MOV . W | @R9, R8     | C0xxC0xx         | C0xxC0xx | C0xx             | C0xx     | C0xx           | xxC0     |
| Longword access | MOV . L | #ADDRAH, R9 |                  |          |                  |          |                |          |
|                 | MOV . L | @R9, R8     | FFxxC0xx         | FFxxC0xx | FFxxC0xx         | C0xxFFxx | FFxxC0xx       | xxC0xxFF |

In this table: #ADDRAH .EQU H'A4000080

#ADDRAL .EQU H'A4000082

Values are shown in hexadecimal for the case where read data is output to an external device via R8.

## Section 20 D/A Converter (DAC)

This LSI includes a D/A converter with two channels.

Figure 20.1 shows a block diagram of the D/A converter.

**Figure 20.1 D/A Converter Block Diagram**

### 20.1 Feature

D/A converter features are listed below.

- Eight-bit resolution
- Two output channels
- Conversion time: maximum 10  $\mu$ s (with 20-pF capacitive load)
- Output voltage: 0 V to  $AV_{CC}$

## 20.2 Input/Output Pin

Table 20.1 summarizes the D/A converter's input and output pins.

**Table 20.1 D/A Converter Pins**

| Pin Name                | Abbreviation | I/O    | Function                            |
|-------------------------|--------------|--------|-------------------------------------|
| Analog power-supply pin | AVcc         | Input  | Analog power supply                 |
| Analog ground pin       | AVss         | Input  | Analog ground and reference voltage |
| Analog output pin 0     | DA0          | Output | Analog output, channel 0            |
| Analog output pin 1     | DA1          | Output | Analog output, channel 1            |

## 20.3 Register Description

The D/A converter has the following registers. Refer to section 23, List of Registers, for more details of the addresses and access sizes.

- D/A data register 0 (DADR0)
- D/A data register 1 (DADR1)
- D/A control register (DACR)

### 20.3.1 D/A Data Registers 0 and 1 (DADR0 and DADR1)

The D/A data registers (DADR0 and DADR1) are 8-bit read/write registers that store the data to be converted. When analog output is enabled, the D/A data register values are constantly converted and output at the analog output pins.

The D/A data registers are initialized to H'00 by a reset.

### 20.3.2 D/A Control Register (DACR)

DACR is an 8-bit read/write register that controls the operation of the D/A converter.

| Bit    | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------|----------|---------------|-----|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7      | DAOE1    | 0             | R/W | D/A Output Enable 1<br>Controls D/A conversion and analog output.<br>0: DA1 analog output is disabled<br>1: Channel-1 D/A conversion and DA1 analog output are enabled                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 6      | DAOE0    | 0             | R/W | D/A Output Enable 0<br>Controls D/A conversion and analog output.<br>0: DA0 analog output is disabled<br>1: Channel-0 D/A conversion and DA0 analog output are enabled                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 5      | DAE      | 0             | R/W | D/A Enable<br>Controls D/A conversion, together with bits DAOE0 and DAOE1. When the DAE bit is cleared to 0, D/A conversion is controlled independently in channels 0 and 1. When this LSI enters standby mode while D/A conversion is enabled, the D/A output is held and the analog power-supply current is equivalent to that during D/A conversion. To reduce the analog power-supply current in standby mode, clear the DAOE0 and DAOE1 bits and disable the D/A output.<br>00—: D/A conversion is disabled in channels 0 and 1<br>010: D/A conversion is enabled in channel 0<br>D/A conversion is disabled in channel 1<br>011: D/A conversion is enabled in channels 0 and 1<br>100: D/A conversion is disabled in channel 0<br>D/A conversion is enabled in channel 1<br>101: D/A conversion is enabled in channels 0 and 1<br>11—: D/A conversion is enabled in channels 0 and 1<br>When the DAE bit is set to 1, even if bits DAOE0 and DAOE1 in DACR and the ADST bit in ADCSR are cleared to 0, the same current is drawn from the analog power supply as during A/D and D/A conversion. |
| 4 to 0 | —        | 1             | R   | Reserved<br>These bits are always read as 1. The write value should always be 1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

## 20.4 Operation

The D/A converter has two built-in D/A conversion circuits that can perform conversion independently.

D/A conversion is performed constantly while enabled in DACR. If the DADR0 or DADR1 value is modified, conversion of the new data begins immediately. The conversion results are output when bits DAOE0 and DAOE1 are set to 1.

An example of D/A conversion on channel 0 is given next. Timing is indicated in figure 20.2.

1. Data to be converted is written in DADR0.
2. Bit DAOE0 is set to 1 in DACR. D/A conversion starts and DA0 becomes an output pin. The converted result is output after the conversion time. The output value is  $(\text{DADR0 contents}/256) \times \text{AV}_{\text{cc}}$ . Output of this conversion result continues until the value in DADR0 is modified or the DAOE0 bit is cleared to 0.
3. If the DADR0 value is modified, conversion starts immediately, and the result is output after the conversion time.
4. When the DAOE0 bit is cleared to 0, DA0 becomes an input pin.

**Figure 20.2 Example of D/A Converter Operation**

## Section 21 Hitachi User-Debugging Interface (H-UDI)

The H-UDI (Hitachi user-debugging interface) performs on-chip debugging which is supported by the SH7706. The H-UDI described here is a serial interface which is pi-compatible with JTAG (Joint Test Action Group, IEEE Standard 1149.1 and IEEE Standard Test Access Port and Boundary-Scan Architecture) specifications.

The H-UDI in the SH7706 supports a boundary scan mode, and is also used for emulator connection.

When using an emulator, H-UDI functions should not be used. Refer to the emulator manual for the method of connecting the emulator.

Figure 21.1 shows the block diagram of the H-UDI.

**Figure 21.1 H-UDI Block Diagram**

## 21.1 Feature

The H-UDI has the following features.

- Support of the E10A emulator
- Standard pin arrangement of JTAG
- Real-time branch trace
- 1-kbyte on-chip RAM for running the high-speed emulation program

## 21.2 Input/Output Pin

Table 21.1 lists the pin configuration of the H-UDI.

**Table 21.1 Pin Configuration**

| Name     | Description                                                                                                                                                                                                                                                                                                                                                                                                            |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TCK      | H-UDI serial data input/output clock pin. Data is serially supplied to the H-UDI from the data input pin (TDI), and output from the data output pin (TDO), in synchronization with this clock.                                                                                                                                                                                                                         |
| TMS      | Mode select input pin. The state of the TAP control circuit is determined by changing this signal in synchronization with TCK. The protocol conforms to the JTAG standard (IEEE Std. 1149.1).                                                                                                                                                                                                                          |
| TRST     | H-UDI reset input pin. Input is accepted asynchronously with respect to TCK, and when low, the H-UDI is reset. See section 21.4.2, Reset Configuration, for more information.                                                                                                                                                                                                                                          |
| TDI      | H-UDI serial data input pin. Data transfer to the H-UDI is executed by changing this signal in synchronization with TCK.                                                                                                                                                                                                                                                                                               |
| TDO      | H-UDI serial data output pin. Data output from the H-UDI is executed by reading this signal in synchronization with TCK.                                                                                                                                                                                                                                                                                               |
| ASEMD0   | ASE mode select pin. If a low level is input at the ASEMD0 pin while the RESETP pin is asserted, ASE mode is entered; if a high level is input, normal operation mode is entered. ASEMD0 pin should be high level when an emulator or H-UDI is not used. In ASE mode, boundary scan and emulator functions can be used. The input level at the ASEMD0 pin should be held for at least one cycle after RESETP negation. |
| ASEBRKAK | Dedicated emulator pin                                                                                                                                                                                                                                                                                                                                                                                                 |

## 21.3 Register Description

The H-UDI has the following registers. Refer to section 23, List of Registers, for more details of the addresses and access sizes.

- Bypass register (SDBPR)
- Instruction register (SDIR)
- Boundary register (SDBSR)

### 21.3.1 Bypass Register (SDBPR)

The bypass register is a 1-bit register that cannot be accessed by the CPU. When the SDIR is set to the bypass mode, the SDBPR is connected between H-UDI pins TDI and TDO.

### 21.3.2 Instruction Register (SDIR)

The instruction register (SDIR) is a 16-bit read-only register. The register is in bypass mode in its initial state. It is initialized by  $\overline{\text{TRST}}$  or in the TAP test-logic-reset state, and can be written by the H-UDI irrespective of the CPU mode. Operation is not guaranteed when a reserved command is set to this register.

| Bit     | Bit Name | Initial Value | R/W | Description                         |
|---------|----------|---------------|-----|-------------------------------------|
| 15      | TI3      | 1             | R   | Test Instruction Bits               |
| 14      | TI2      | 1             | R   | Cannot be written by the CPU.       |
| 13      | TI1      | 1             | R   | 0000: EXTEST                        |
| 12      | TI0      | 1             | R   | 0100: SAMPLE/PRELOAD                |

Note: X Don't care

### 21.3.3 Boundary Scan Register (SDBSR)

The boundary scan register (SDBSR) is a shift register, located on the PAD, for controlling the input/output pins of this LSI.

Using the EXTEST and SAMPLE/PRELOAD commands, a boundary scan test conforming to the JTAG standard can be carried out. Table 21.2 shows the correspondence between this LSI's pins and boundary scan register bits.

**Table 21.2 This LSI's Pins and Boundary Scan Register Bits**

| Bit | Pin Name   | I/O | Bit | Pin Name   | I/O |

## 21.4 H-UDI Operations

### 21.4.1 TAP Controller

Figure 21.2 shows the internal states of TAP controller. State transitions basically conform with the JTAG standard.

**Figure 21.2 TAP Controller State Transitions**

Note: The transition condition is the TMS value on the rising edge of TCK. The TDI value is sampled on the rising edge of TCK; shifting occurs on the falling edge of TCK. The TDO value changes on the TCK falling edge. The TDO is at high impedance, except with shift-DR (shift-SR) and shift-IR states. During the change to TRSTN = 0, there is a transition to test-logic-reset asynchronously with TCK.

## 21.4.2 Reset Configuration

**Table 21.3 Reset Configuration**

| $\overline{\text{ASDMD0}}^{*1}$ | $\overline{\text{RESETP}}$ | $\overline{\text{TRST}}$ | Chip State                                                                                                                             |
|---------------------------------|----------------------------|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------|

Notes: 1. Performs normal operation mode and ASE mode settings

$\overline{\text{ASEMD0}} = \text{H}$ , normal operation mode

$\overline{\text{ASEMD0}} = \text{L}$ , ASE mode

$\overline{\text{ASEMD0}}$  pin should be high level when an emulator or H-UDI is not used.

- During ASE mode, reset hold is enabled by setting  $\overline{\text{RESETP}}$  and  $\overline{\text{TRST}}$  pins at low level for a constant cycle. In this state, the CPU does not start up, even if  $\overline{\text{RESETP}}$  is set to high level. When  $\overline{\text{TRST}}$  is set to high level, H-UDI operation is enabled, but the CPU does not start up. The reset hold state is cancelled by the following:
  - Boot request from H-UDI (boot sequence)
  - Another  $\overline{\text{RESETP}}$  assert (power-on reset)
- ASE mode can be divided by two modes: a mode to execute the firmware program of the emulator (ASE break mode) and a mode to execute the user program (ASE user mode).

### 21.4.3 H-UDI Reset

An H-UDI reset is executed by setting an H-UDI reset assert command in SDIR. An H-UDI reset is of the same kind as a power-on reset. An H-UDI reset is released by inputting an H-UDI reset negate command.

The interval required between the H-UDI reset assert command and the H-UDI reset negate command is the same as the time for which the RESETP pin is held low in order to execute a power-on reset.

Figure 21.3 H-UDI Reset

### 21.4.4 H-UDI Interrupt

The H-UDI interrupt function generates an interrupt by setting a command from the H-UDI in the SDIR. An H-UDI interrupt is a general exception/interrupt operation, resulting in a branch to an address based on the VBR value plus offset, and return by the RTE instruction. This interrupt request has a fixed priority level of 15.

H-UDI interrupts are not accepted in sleep mode or standby mode.

### 21.4.5 Bypass

The JTAG-based bypass mode for the H-UDI pins can be selected by setting a command from the H-UDI in the SDIR.

### 21.4.6 Using H-UDI to Recover from Sleep Mode

It is possible to recover from sleep mode by setting a command (0001) from the H-UDI in SDIR.

## 21.5 Boundary Scan

A command can be set in SDIR by the H-UDI to place the H-UDI pins in the boundary scan mode stipulated by JTAG.

### 21.5.1 Supported Instructions

This LSI supports the three essential instructions defined in the JTAG standard (BYPASS, SAMPLE/PRELOAD, and EXTEST).

**BYPASS:** The BYPASS instruction is an essential standard instruction that operates the bypass register. This instruction shortens the shift path to speed up serial data transfer involving other chips on the printed circuit board. While this instruction is executing, the test circuit has no effect on the system circuits. The instruction code is 1111.

**SAMPLE/PRELOAD:** The SAMPLE/PRELOAD instruction inputs values from this LSI's internal circuitry to the boundary scan register, outputs values from the scan path, and loads data onto the scan path. When this instruction is executing, this LSI's input pin signals are transmitted directly to the internal circuitry, and internal circuit values are directly output externally from the output pins. This LSI's system circuits are not affected by execution of this instruction. The instruction code is 0100.

In a SAMPLE operation, a snapshot of a value to be transferred from an input pin to the internal circuitry, or a value to be transferred from the internal circuitry to an output pin, is latched into the boundary scan register and read from the scan path. Snapshot latching is performed in synchronization with the rise of TCK in the Capture-DR state. Snapshot latching does not affect normal operation of this LSI.

In a PRELOAD operation, an initial value is set in the parallel output latch of the boundary scan register from the scan path prior to the EXTEST instruction. Without a PRELOAD operation, when the EXTEST instruction was executed an undefined value would be output from the output pin until completion of the initial scan sequence (transfer to the output latch) (with the EXTEST instruction, the parallel output latch value is constantly output to the output pin).

**EXTEST:** This instruction is provided to test external circuitry when this LSI is mounted on a printed circuit board. When this instruction is executed, output pins are used to output test data (previously set by the SAMPLE/PRELOAD instruction) from the boundary scan register to the printed circuit board, and input pins are used to latch test results into the boundary scan register from the printed circuit board. If testing is carried out by using the EXTEST instruction N times, the Nth test data is scanned-in when test data (N-1) is scanned out.

Data loaded into the output pin boundary scan register in the Capture-DR state is not used for external circuit testing (it is replaced by a shift operation).

The instruction code is 0000.

### 21.5.2 Notes for Boundary Scan

1. Boundary scan mode does not cover clock-related signals (EXTAL, EXTAL2, XTAL, XTAL2, CKIO).
2. Boundary scan mode does not cover reset-related signals ( $\overline{\text{RESETP}}$ ,  $\overline{\text{RESETM}}$ , CA).
3. Boundary scan mode does not cover H-UDI-related signals (TCK, TDI, TDO, TMS, TRST).
4. When a boundary scan test is carried out, ensure that the CKIO clock operates constantly.

The CKIO frequency range is as follows:

Minimum: 1 MHz

Maximum: Maximum frequency for respective clock mode specified in the CPG section

Set pins MD[2:0] to the clock mode to be used.

After powering on, wait for the CKIO clock to stabilize before performing a boundary scan test.

5. Fix the  $\overline{\text{RESETP}}$  pin low.
6. Fix the CA pin high, and the  $\overline{\text{ASEMD0}}$  pin low.

## 21.6 Usage Note

1. An H-UDI command other than an H-UDI interrupt, once set, will not be modified as long as another command is not re-issued from the H-UDI. An H-UDI interrupt command, however, will be changed to a bypass command once set.
2. Because chip operations are suspended in standby mode, H-UDI commands are not accepted. However, the TAP controller remains in operation at this time.
3. The H-UDI is used for emulator connection. Therefore, H-UDI functions cannot be used when using an emulator.

## 21.7 Advanced User Debugger (AUD)

The AUD is a function exclusively for use by an emulator. Refer to the User's Manual for the relevant emulator for details of the AUD.

## Section 22 Power-Down Modes

In the power-down modes, all CPU and some on-chip supporting module functions are halted. This lowers power consumption.

The SH7706 has four power-down modes:

1. Sleep mode
2. Software standby mode
3. Module standby function (TMU, RTC, SCI, UBC, DMAC, DAC, ADC, and SCIF on-chip supporting modules)
4. Hardware standby mode

Table 22.1 shows the transition conditions for entering the modes from the program execution state, as well as the CPU and supporting module states in each mode and the procedures for canceling each mode.

**Table 22.1 Power-Down Modes**

| Mode                    | Transition Conditions                                         | State |                        |              |                |                            |                |                 | Canceling Procedure                |
|-------------------------|---------------------------------------------------------------|-------|------------------------|--------------|----------------|----------------------------|----------------|-----------------|------------------------------------|
|                         |                                                               | CPG   | CPU                    | CPU Register | On-Chip Memory | On-Chip Peripheral Modules | Pins           | External Memory |                                    |
| Sleep mode              | Execute SLEEP instruction with STBY bit cleared to 0 in STBCR | Runs  | Halts (Register: held) | Held         | Held           | Run                        | Held           | Refresh         | 1. Interrupt<br>2. Reset           |
| Software standby mode   | Execute SLEEP instruction with STBY bit set to 1 in STBCR     | Halts | Halts (Register: held) | Held         | Held           | Halt* <sup>1</sup>         | Held           | Self-refresh    | 1. Interrupt<br>2. Reset           |
| Module standby function | Set MSTP bit of STBCR to 1                                    | Runs  | Runs * <sup>4</sup>    | Held         | Held           | Specified module halts     | * <sup>2</sup> | Refresh         | 1. Clear MSTP bit to 0<br>2. Reset |
| Hardware standby mode   | Drive CA pin low                                              | Halts | Halts                  | Held         | Held           | Halt* <sup>3</sup>         | Held           | Self-refresh    | Power-on reset                     |

- Notes:
1. The RTC still runs if the START bit in RCR2 is set to 1 (see section 13, Realtime Clock (RTC)). TMU still runs when output of the RTC is used as input to its counter (see section 12, Timer (TMU)).
  2. Depends on the on-chip supporting module.  
TMU external pin: Held  
SCI external pin: Reset
  3. The RTC still runs if the START bit in RCR2 is set to 1. TMU does not run.
  4. When the LSI enters sleep mode, the CPU halts.

## 22.1 Input/Output Pin

Table 22.2 lists the pins used for the power-down modes.

**Table 22.2 Pin Configuration**

| Pin Name           | Symbol  | I/O | Description                                    |
|--------------------|---------|-----|------------------------------------------------|
| Processing state 1 | STATUS1 | O   | Operating state of the processor.              |
| Processing state 0 | STATUS0 |     | STATUS1      STATUS0      state                |
|                    |         |     | High-level      High-level      Reset          |
|                    |         |     | High-level      Low-level      Sleep mode      |
|                    |         |     | Low-level      High-level      Standby mode    |
|                    |         |     | Low-level      Low-level      Normal operation |

## 22.2 Register Description

These are two control registers for the power-down modes. Refer to section 23, List of Registers, for more details of the addresses and access sizes.

- Standby control register (STBCR)
- Standby control register 2 (STBCR2)

### 22.2.1 Standby Control Register (STBCR)

The standby control register (STBCR) is an 8-bit read/write register that sets the power-down mode.

| Bit | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                     |
|-----|----------|---------------|-----|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7   | STBY     | 0             | R/W | Software Standby<br>Specifies transition to software standby mode.<br>0: Executing SLEEP instruction puts the chip into sleep mode.<br>1: Executing SLEEP instruction puts the chip into software standby mode. |
| 6   | —        | 0             | R   | Reserved                                                                                                                                                                                                        |
| 5   | —        | 0             | R   | These bits are always read as 0. The write value should always be 0.                                                                                                                                            |

| Bit | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                                                                                                                                                                 |

### 22.2.2 Standby Control Register 2 (STBCR2)

The standby control register 2 (STBCR2) is a read/write 8-bit register that sets the power-down mode.

| Bit | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                                                                                                                                                                                             |
|-----|----------|---------------|-----|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7   | —        | 0             | R   | Reserved<br><br>This bit is always read as 0. The write value should always be 0.                                                                                                                                                                                                                                                                                                       |

## 22.3 Operation

### 22.3.1 Sleep Mode

- **Transition to Sleep Mode**

Executing the SLEEP instruction when the STBY bit in STBCR is 0 causes a transition from the program execution state to sleep mode. Although the CPU halts immediately after executing the SLEEP instruction, the contents of its internal registers remain unchanged. The on-chip supporting modules continue to run during sleep mode and the clock continues to be output to the CKIO pin. In sleep mode, the STATUS1 pin is set high and the STATUS0 pin low.

- **Canceling Sleep Mode**

Sleep mode is canceled by an interrupt (NMI, IRQ, IRL, on-chip supporting module) or reset. Interrupts are accepted during sleep mode even when the BL bit in the SR register is 1. If necessary, save SPC and SSR in the stack before executing the SLEEP instruction.

**Canceling with an Interrupt:** When an NMI, IRQ, IRL or on-chip supporting module interrupt occurs, sleep mode is canceled and interrupt exception processing is executed. A code indicating the interrupt source is set in the INTEVT and INTEVT2 registers.

**Canceling with a Reset:** Sleep mode is canceled by a power-on reset or a manual reset.

## 22.3.2 Software Standby Mode

### • Transition to Software Standby Mode

To enter standby mode, set the STBY bit to 1 in STBCR, then execute the SLEEP instruction. The chip moves from the program execution state to software standby mode. In software standby mode, power consumption is greatly reduced by halting not only the CPU, but the clock and on-chip supporting modules as well. The clock output from the CKIO pin also halts. CPU and cache register contents are held, but some on-chip supporting modules are initialized. Table 22.3 lists the states of registers in software standby mode.

**Table 22.3 Register States in Software Standby Mode**

| Module                              | Registers Initialized | Registers Retaining Data  |
|-------------------------------------|-----------------------|---------------------------|
| Interrupt controller (INTC)         | —                     | All registers             |
| On-chip clock pulse generator (CPG) | —                     | All registers             |
| User Break controller (UBC)         | —                     | All registers             |
| Bus state controller (BSC)          | —                     | All registers             |
| Timer unit (TMU)                    | TSTR register         | Registers other than TSTR |
| Realtime clock (RTC)                | —                     | All registers             |
| A/D converter (ADC)                 | All registers         | —                         |
| D/A converter (DAC)                 | —                     | All registers             |

The procedure for moving to software standby mode is as follows:

1. Clear the TME bit in the WDT's timer control register (WTCSR) to 0 to stop the WDT. Set the WDT's timer counter (WTCNT) and the CKS2 to CKS0 bits of the WTCSR register to appropriate values to secure the specified oscillation settling time.
2. After the STBY bit in the STBCR register is set to 1, a SLEEP instruction is executed.
3. Software standby mode is entered and the clocks within the chip are halted. The STATUS1 pin output goes low and the STATUS0 pin output goes high.

- **Canceling Software Standby Mode**

Standby mode is canceled by an interrupt (NMI, IRQ\*<sup>1</sup>, IRL\*<sup>1</sup>, or on-chip supporting module)\*<sup>2</sup> or a reset.

**Canceling with an Interrupt:** The on-chip WDT can be used for hot starts. When the chip detects an NMI, IRL, IRQ,\*<sup>1</sup> or on-chip supporting module (except the interval timer)\*<sup>2</sup> interrupt, the clock will be supplied to the entire chip and software standby mode canceled after the time set in the WDT's timer control/status register has elapsed. The STATUS1 and STATUS0 pins both go low. Interrupt processing then begins and a code indicating the interrupt source is set in the INTEVT and INTEVT2 registers. After branching to the interrupt processing routine occurs, clear the STBY bit in the STBCR register. The WTCNT stops automatically. If the STBY bit is not cleared, WTCNT continues operation and transits to the standby mode\*<sup>3</sup> when it reaches H'80. This function prevents the data from being destroyed due to a rising voltage under an unstable power supply. Interrupts are accepted during software standby mode even when the BL bit in the SR register is 1. If necessary, save SPC and SSR in the stack before executing the SLEEP instruction. Immediately after an interrupt is detected, the phase of the clock output of the CKIO pin may be unstable, until the processor starts interrupt processing. (The canceling condition is that the  $\overline{\text{IRL3}}$  to  $\overline{\text{IRL0}}$  level is higher than the mask level in the I3 to I0 bits in the SR register.)

- Notes:
1. Software Standby mode can be canceled using  $\overline{\text{IRL3}}$  to  $\overline{\text{IRL0}}$  or IRQ4 to IRQ0.
  2. Software standby mode can be canceled with an RTC or TMU (only when running on the RTC clock) interrupt.
  3. Standby mode should be canceled by power-on resets. Operations at manual resets or during interrupt input are not guaranteed.

**Figure 22.1 Canceling Software Standby Mode with STBCR.STBY**

**Canceled with a Reset:** Standby mode can be canceled with a reset (power-on or manual). Keep the RESETP pin and RESETM pin low until the clock oscillation settles.

- **Clock Pause Function**

In software standby mode, the clock input from the EXTAL pin or CKIO pin can be halted and the frequency can be changed. This function is used as follows:

1. Enter software standby mode using the appropriate procedures.
2. Once software standby mode is entered and the clock stopped within the chip, the STATUS1 pin output is low and the STATUS0 pin output is high.
3. Once the STATUS1 pin goes low and the STATUS0 pin goes high, the input clock is stopped or the frequency is changed.
4. When the frequency is changed, an NMI,  $\overline{\text{IRL}}$ , IRQ or on-chip supporting module (except the internal timer) interrupt is input after the change. When the clock is stopped, the same interrupts are input after the clock is applied.
5. After the time set in the WDT has elapsed, the clock starts being applied internally within the chip, the STATUS1–STATUS0 pins both go low, interrupts are handled, and operation resumes.

### 22.3.3 Module Standby Function

- **Transition to Module Standby Function**

Setting the standby control register MSTP8 to MSTP0 bits to 1 halts the supply of clocks to the corresponding on-chip supporting modules. This function can be used to reduce the power consumption in sleep mode. The module standby function holds the state prior to halt of the external pins of the on-chip supporting modules. TMU external pins hold their state prior to the halt. SCI external pins go to the reset state. With a few exceptions, all registers hold their values.

| Bit   | Value | Description                                                              |
|-------|-------|--------------------------------------------------------------------------|
| MSTP8 | 0     | UBC runs.                                                                |
|       | 1     | Supply of clock to UBC halted.                                           |
| MSTP7 | 0     | DMAC runs.                                                               |
|       | 1     | Supply of clock to DMAC halted.                                          |
| MSTP6 | 0     | DAC runs.                                                                |
|       | 1     | Supply of clock to DAC halted.                                           |
| MSTP5 | 0     | ADC runs.                                                                |
|       | 1     | Supply of clock to ADC halted, and all registers initialized.            |
| MSTP4 | 0     | SCIF runs.                                                               |
|       | 1     | Supply of clock to SCIF halted.                                          |
| MSTP2 | 0     | TMU runs.                                                                |
|       | 1     | Supply of clock to TMU halted. Registers initialized.* <sup>1</sup>      |
| MSTP1 | 0     | RTC runs.                                                                |
|       | 1     | Supply of clock to RTC halted. Register access prohibited.* <sup>2</sup> |
| MSTP0 | 0     | SCI runs.                                                                |
|       | 1     | Supply of clock to SCI halted.                                           |

Notes: 1. The registers initialized are the same as in the software standby mode (table 8.4).

2. The counter runs.

- **Clearing the Module Standby Function**

The module standby function can be cleared by clearing the MSTP8 to MSTP0 bits to 0, or by a power-on reset or manual reset.

### 22.3.4 Timing of STATUS Pin Changes

The timing of STATUS1 and STATUS0 pin changes is shown in figures 22.2 through 22.9

- **Timing for Resets**

**Power-On Reset:**

**Figure 22.2 Power-On Reset STATUS Output**

**Manual Reset:**

**Figure 22.3 Manual Reset STATUS Output**

- **Timing for Canceling Software Standbys**

**Software Standby to Interrupt:**

- Notes:
1. Standby: LH (STATUS1 low, STATUS0 high)
  2. Normal: LL (STATUS1 low, STATUS0 low)

**Figure 22.4 Software Standby to Interrupt STATUS Output**

### Software Standby to Power-On Reset:

- Notes:
1. When software standby mode is cleared with a power-on reset, the WDT does not count. Keep RESETP low during the PLL's oscillation settling time.
  2. Reset: HH (STATUS1 high, STATUS0 high)
  3. Standby: LH (STATUS1 low, STATUS0 high)
  4. Normal: LL (STATUS1 low, STATUS0 low)
  5. Bcyc: Bus clock cycle
  6. Undefined

**Figure 22.5 Software Standby to Power-On Reset STATUS Output**

## Software Standby to Manual Reset:

**Figure 22.6 Software Standby to Manual Reset STATUS Output**

## • Timing for Canceling Sleep Mode

### Sleep to Interrupt:

**Figure 22.7 Sleep to Interrupt STATUS Output**

## Sleep to Power-On Reset:

- Notes:
1. When the PLL1's multiplication ratio is changed by a power-on reset, keep  $\overline{\text{RESETP}}$  low during the PLL's oscillation settling time.
  2. Reset: HH (STATUS1 high, STATUS0 high)
  3. Sleep: HL (STATUS1 high, STATUS0 low)
  4. Normal: LL (STATUS1 low, STATUS0 low)
  5. Bcyc: Bus clock cycle
  6. Undefined

**Figure 22.8 Sleep to Power-On Reset STATUS Output**

## Sleep to Manual Reset:

- Notes:
1. Keep  $\overline{\text{RESETM}}$  low until STATUS becomes reset.
  2. Reset: HH (STATUS1 high, STATUS0 high)
  3. Sleep: HL (STATUS1 high, STATUS0 low)
  4. Normal: LL (STATUS1 low, STATUS0 low)
  5. Bcyc: Bus clock cycle

**Figure 22.9 Sleep to Manual Reset STATUS Output**

### 22.3.5 Hardware Standby Function

- **Transition to Hardware Standby Mode**

Driving the CA pin low causes a transition to hardware standby mode. In hardware standby mode, all modules except those operating on an RTC clock are halted, as in the software standby mode entered on execution of a SLEEP instruction ((software) standby mode).

Hardware standby mode differs from software standby mode as follows.

1. Interrupts and manual resets are not accepted.
2. The TMU does not operate.

Operation when a low-level signal is input at the CA pin depends on the CPG state, as follows.

1. In software standby mode  
The clock remains stopped and the chip enters the hardware standby state. Acceptance of interrupts and manual resets is disabled, TCLK output is fixed low, and the TMU halts.
2. During WDT operation when software standby mode is canceled by an interrupt  
The chip enters hardware standby mode after standby mode is canceled and the CPU resumes operation.
3. In sleep mode  
The chip enters hardware standby mode after sleep mode is canceled and the CPU resumes operation.

Hold the CA pin low in hardware standby mode.

In hardware standby mode, the LSI can supply power only to the RTC power-supply pin.

- **Canceling Hardware Standby Mode**

Hardware standby mode can only be canceled by a power-on reset.

When the CA pin is driven high while the  $\overline{\text{RESETP}}$  pin is low, clock oscillation is started. Hold the  $\overline{\text{RESETP}}$  pin low until clock oscillation stabilizes. When the  $\overline{\text{RESETP}}$  pin is driven high, the CPU begins power-on reset processing.

If an interrupt or manual reset is input, correct operation cannot be guaranteed.

## • Hardware Standby Mode Timing

Figures 22.10 and 22.11 show examples of pin timing in hardware standby mode.

The CA pin is sampled using EXTAL2 (32.768 kHz), and a hardware standby request is only recognized when the pin is low for two consecutive clock cycles.

The CA pin must be held low while the chip is in hardware standby mode.

Clock oscillation starts when the CA pin is driven high after the  $\overline{\text{RESETP}}$  pin is driven low.

**Figure 22.10 Hardware Standby Mode  
(When CA Goes Low in Normal Operation)**

**Figure 22.11 Hardware Standby Mode Timing**  
**(When CA Goes Low during WDT Operation on Standby Mode Cancellation)**

## Section 23 List of Registers

### 23.1 Register Address Map

| Control Register | Module* <sup>1</sup> | Bus* <sup>2</sup> | Address     | Size (Bits) | Access Size (Bits)* <sup>3</sup> |
|------------------|----------------------|-------------------|-------------|-------------|----------------------------------|
| PTEH             | CCN                  | L                 | H'FFFFFFFF0 | 32          | 32                               |
| PTL              |                      | L                 | H'FFFFFFFF4 | 32          | 32                               |
| TTB              |                      | L                 | H'FFFFFFFF8 | 32          | 32                               |

Notes: 1. Modules:

CCN: Cache controller

UBC: User break controller

CPG: Clock pulse generator

BSC: Bus state controller

RTC: Realtime clock

INTC: Interrupt controller

TMU: Timer unit

SCI: Serial communication interface

2. Internal buses:

L: CPU, CCN, cache, and TLB connected

I: BSC, cache, DMAC, INTC, CPG, and H-UDI connected

P: BSC and peripheral modules (RTC, TMU, SCI, SCIF, A/D, D/A, DMAC, ports, CMT) connected

3. The access size shown is for control register access (read/write). An incorrect result will be obtained if a different size from that shown is used for access.

4. With 16-bit access, it is not possible to read data in two registers simultaneously.

5. With 32-bit access, it is not possible to read data in the register at [accessed address + 2] simultaneously.

## 23.2 Register Bits

The following are the bit-name of each registers. The 16-bit and 32-bit registers are shown by tow and four 8-bit rows, respectively.

| Register | Bit 7        | Bit 6 | Bit 5 | Bit 4        | Bit 3 | Bit 2 | Bit 1 | Bit 0 | Module |
|----------|--------------|-------|-------|--------------|-------|-------|-------|-------|--------|

- Notes:
1. Some bits are not initialized.
  2. These bits are not initialized at a power-on reset by the WDT.
  3. Some bits are initialized.
  4. Initialized on asserting state of  $\overline{\text{TRST}}$  or on Test-Logic-Reset state of TAP.

# Section 24 Electrical Characteristics

## 24.1 Absolute Maximum Ratings

Table 24.1 shows the absolute maximum ratings.

**Table 24.1 Absolute Maximum Ratings**

| Item                            | Symbol                                       | Rating             | Unit |
|---------------------------------|----------------------------------------------|--------------------|------|
| Power supply voltage (I/O)      | VccQ                                         | −0.3 to 4.2        | V    |
| Power supply voltage (internal) | Vcc<br>Vcc − PLL1<br>Vcc − PLL2<br>Vcc − RTC | −0.3 to 2.5        | V    |
| Input voltage (except port J)   | Vin                                          | −0.3 to VccQ + 0.3 | V    |
| Input voltage (port J)          | Vin                                          | −0.3 to AVcc + 0.3 | V    |
| Analog power-supply voltage     | AVcc                                         | −0.3 to 4.6        | V    |
| Analog input voltage            | V <sub>AN</sub>                              | −0.3 to AVcc + 0.3 | V    |
| Operating temperature           | Topr                                         | −20 to 75          | °C   |
| Storage temperature             | Tstr                                         | −55 to 125         | °C   |

**Caution:** Operating the chip in excess of the absolute maximum rating may result in permanent damage.

- Order of turning on or off 1.9 V power (Vcc, Vcc-PLL1, Vcc-PLL2, Vcc-RTC) and 3.3 V power (VccQ, AVcc):
  1. The voltage of 1.9 V power should not be higher than that of 3.3 V power.  
The period when only 3.3 V power is turned on should be less than 1 ms. This period should be as short as possible.
  2. Until voltage is applied to all power supplies, a high level is input at the CA pin, and a low level is input at the  $\overline{\text{RESETP}}$  pin, and CKIO clocks are equal to or below 4 clocks, internal circuits remain unsettled, and so pin states are also undefined. The system design must ensure that these undefined states do not cause erroneous system operation. When the CA pin is at a low level, the low level of the  $\overline{\text{RESETP}}$  pin is not accepted.

Waveforms at power-on are shown in the following figure.

Note: \* Except power/GND, clock related, and analog pins

### Power-On Sequence

## 24.2 DC Characteristics

Tables 24.2 and 24.3 list DC characteristics.

**Table 24.2 DC Characteristics (Ta = –20 to 75°C)**

|                             | Idle                          | —   | 0.01 | 5.0 | μA   | Ta = 25°C              |

- Notes: 1. Regardless of whether PLL or RTC is used, connect Vcc – PLL and Vcc – RTC to Vcc, and Vss – PLL and Vss – RTC to Vss.
2. AVcc must be under condition of  $V_{ccQ} - 0.3 \text{ V} \leq AV_{cc} \leq V_{ccQ} + 0.3 \text{ V}$ . If the A/D and D/A converters are not used, do not leave the AVcc and AVss pins open. Connect AVcc to VccQ, and connect AVss to VssQ.
3. Current dissipation values shown are the values at which all output pins are without load  
under conditions of  $V_{IH, \min} = V_{ccQ} - 0.5 \text{ V}$ ,  $V_{IL, \max} = 0.5 \text{ V}$ .

Notes: \*1. No external bus cycles except refresh cycles.

\*2. Total current of Vcc, Vcc – PLL1, and Vcc – PLL2

\*3. Current of VccQ

\*4. Current of Vcc – RTC

\*5. Only in software standby mode

**Table 24.3 Permitted Output Current Values**

(VccQ =  $3.3 \pm 0.3 \text{ V}$ , Vcc =  $1.9 \pm 0.15 \text{ V}$ , AVcc =  $3.3 \pm 0.3 \text{ V}$ , Ta = -20 to 75°C)

| Item                                            | Symbol           | Min | Typ | Max | Unit |
|-------------------------------------------------|------------------|-----|-----|-----|------|
| Output low-level permissible current (per pin)  | $I_{OL}$         | —   | —   | 2.0 | mA   |
| Output low-level permissible current (total)    | $\sum I_{OL}$    | —   | —   | 120 | mA   |
| Output high-level permissible current (per pin) | $-I_{OH}$        | —   | —   | 2.0 | mA   |
| Output high-level permissible current (total)   | $\sum (-I_{OH})$ | —   | —   | 40  | mA   |

Caution: To ensure LSI reliability, do not exceed the value for output current given in Table 24.3.

## 24.3 AC Characteristics

In general, inputting for this LSI should be clock synchronous. Keep the setup and hold times for each input signal unless otherwise specified.

Operating conditons are as follows:

$V_{CCQ}=3.3\pm0.3V$

$V_{CC}=1.9\pm0.15V$

$AV_{CC}=3.3\pm0.3V$

$T_a=-20$  to  $75^{\circ}C$

**Table 24.4 Operating Frequency Range**

| Item                |                   | Symbol | Min  | Typ | Max    | Unit | Remarks |
|---------------------|-------------------|--------|------|-----|--------|------|---------|
| Operating frequency | CPU, cache, TLB   | f      | 25   | —   | 133.34 | MHz  |         |
|                     | External bus      |        | 25   | —   | 66.67  |      |         |
|                     | Peripheral module |        | 6.25 | —   | 33.34  |      |         |

### 24.3.1 Clock Timing

**Table 24.5 Clock Timing**

| Item                                           | Symbol      | Min  | Max   | Unit | Figure |

## 24.3.2 Control Signal Timing

**Table 24.6 Control Signal Timing**

| Item                                   | Symbol      | Min              | Max | Unit | Figure |
|----------------------------------------|-------------|------------------|-----|------|--------|
| RESETP pulse width                     | $t_{RESPW}$ | 20* <sup>3</sup> | —   | tcyc | 24.11, |
| RESETP setup time* <sup>1</sup>        | $t_{RESPS}$ | 20               | —   | ns   | 24.12  |
| RESETP hold time                       | $t_{RESPH}$ | 2                | —   | ns   |        |
| RESETM pulse width                     | $t_{RESMW}$ | 12* <sup>4</sup> | —   | tcyc |        |
| RESETM setup time                      | $t_{RESMS}$ | 6                | —   | ns   |        |
| RESETM hold time                       | $t_{RESMH}$ | 34               | —   | ns   |        |
| BREQ setup time                        | $t_{BREQS}$ | 6                | —   | ns   | 24.14  |
| BREQ hold time                         | $t_{BREQH}$ | 4                | —   | ns   |        |
| NMI setup time * <sup>1</sup>          | $t_{NMIS}$  | 10               | —   | ns   | 24.12, |
| NMI hold time                          | $t_{NMIH}$  | 4                | —   | ns   | 24.13  |
| IRQ5 to IRQ0 setup time * <sup>1</sup> | $t_{IRQS}$  | 10               | —   | ns   |        |
| IRQ5 to IRQ0 hold time                 | $t_{IRQH}$  | 4                | —   | ns   |        |
| IRQOUT delay time                      | $t_{IRQOD}$ | —                | 10  | ns   |        |
| BACK delay time                        | $t_{BACKD}$ | —                | 10  | ns   | 24.14, |
| STATUS1, STATUS0 delay time            | $t_{STD}$   | —                | 10  | ns   | 24.15  |
| Bus tri-state delay time 1             | $t_{BOFF1}$ | 0                | 15  | ns   |        |
| Bus tri-state delay time 2             | $t_{BOFF2}$ | 0                | 15  | ns   |        |
| Bus buffer-on time 1                   | $t_{BON1}$  | 0                | 15  | ns   |        |
| Bus buffer-on time 2                   | $t_{BON2}$  | 0                | 15  | ns   |        |

- Notes: 1. RESETP, NMI, and IRQ5 to IRQ0 are asynchronous. Changes are detected at the clock fall when the setup shown is used. When the setup cannot be used, detection can be delayed until the next clock falls.
2. The upper limit of the external bus clock is 66 MHz.
3. In the standby mode, when XTAL oscillation continues,  $t_{RESPH} = t_{OSC1}$  (100μs), when XTAL oscillation stops,  $t_{RESPW} = t_{OSC2}$  (10 ms). In the sleep mode,  $t_{RESPW} = t_{PLL1}$  (100 μs). When the clock multiplication ratio is changed,  $t_{RESPW} = t_{PLL1}$  (100 μs).
4. In the standby mode,  $t_{RESMW} = t_{OSC2}$  (10 ms). In the sleep mode, RESETM must be kept low until STATUS (0-1) changes to reset (HH). When the clock multiplication ratio is changed, RESETM must be kept low until STATUS (0-1) changes to reset (HH).

tcyc: P $\phi$  cycle

**Figure 24.60 External Trigger Input Timing**

**Figure 24.61 A/D Conversion Timing**

### 24.3.11 AC Characteristics Measurement Conditions

- I/O signal reference level: 1.5 V ( $V_{CCQ}/2 = 3.3 \pm 0.3$  V,  $V_{CC} = 1.9 \pm 0.15$  V)
- Input pulse level:  $V_{SSQ}$  to 3.0 V (where  $\overline{RESETP}$ ,  $\overline{RESETM}$ ,  $\overline{ASEMD0}$ ,  $\overline{ADTRG}$ ,  $\overline{TRST}$ ,  $\overline{CA}$ ,  $\overline{NMI}$ ,  $\overline{IRQ5}$  to  $\overline{IRQ0}$ ,  $\overline{CKIO}$ , and MD5 to MD0 are within  $V_{SSQ}$  to  $V_{CCQ}$ )
- Input rise and fall times: 1 ns

- Notes:
1.  $C_L$  is the total value that includes the capacitance of measurement instruments, etc., and is set as follows for each pin.  
30pF:  $\overline{CKIO}$ ,  $\overline{RASx}$ ,  $\overline{CASxx}$ ,  $\overline{CS0}$ ,  $\overline{CS2}$  to  $\overline{CS6}$ ,  $\overline{CE2A}$ ,  $\overline{CE2B}$ ,  $\overline{BACK}$   
50pF: All other pins
  2.  $I_{OL}$  and  $I_{OH}$  are the values shown in table 23.3.

**Figure 24.62 Output Load Circuit**

24.3.12 Delay Time Variation Due to Load Capacitance

A graph (reference data) of the variation in delay time when a load capacitance greater than that stipulated (30 pF) is connected to this LSI's pins is shown below. The graph shown in Figure 24.63 should be taken into consideration in the design process if the stipulated capacitance is exceeded in connecting an external device.

If the connected load capacitance exceeds the range shown in Figure 24.63 the graph will not be a straight line.

Figure 24.63 Load Capacitance vs. Delay Time

## 24.4 A/D Converter Characteristics

Table 24.11 lists the A/D converter characteristics.

**Table 24.11 A/D Converter Characteristics**

( $V_{CCQ} = 3.3 \pm 0.3$  V,  $V_{CC} = 1.9 \pm 0.15$  V,  $AV_{CC} = 3.3 \pm 0.3$  V,  $T_a = -20$  to  $75^\circ\text{C}$ )

| Item                                                | Min | Typ | Max       | Unit          |
|-----------------------------------------------------|-----|-----|-----------|---------------|
| Resolution                                          | 10  | 10  | 10        | bits          |
| Conversion time                                     | 15  | —   | —         | $\mu\text{s}$ |
| Analog input capacitance                            | —   | —   | 20        | pF            |
| Permissible signal-source (single-source) impedance | —   | —   | 5         | k $\Omega$    |
| Nonlinearity error                                  | —   | —   | $\pm 3.0$ | LSB           |
| Offset error                                        | —   | —   | $\pm 2.0$ | LSB           |
| Full-scale error                                    | —   | —   | $\pm 2.0$ | LSB           |
| Quantization error                                  | —   | —   | $\pm 0.5$ | LSB           |
| Absolute accuracy                                   | —   | —   | $\pm 4.0$ | LSB           |

## 24.5 D/A Converter Characteristics

Table 24.12 lists the D/A converter characteristics.

**Table 24.12 D/A Converter Characteristics**

( $V_{CCQ} = 3.3 \pm 0.3$  V,  $V_{CC} = 1.9 \pm 0.15$  V,  $AV_{CC} = 3.3 \pm 0.3$  V,  $T_a = -20$  to  $75^\circ\text{C}$ )

| Item              | Min | Typ       | Max       | Unit          | Test Conditions              |
|-------------------|-----|-----------|-----------|---------------|------------------------------|

|  | Switch between crystal resonator and crystal oscillator input (input from EXTAL) | EXTAL                      |

## B. Pin Functions

### B.1 Pin Functions

Table B.1 shows pin states during resets, power-down states, and the bus-released states.

**Table B.1 Pin States during Resets, Power-Down States, and Bus-Released State**

| Category       | Pin                        | Reset            |                  | Power-Down        |                  | Bus Released     |
|----------------|----------------------------|------------------|------------------|-------------------|------------------|------------------|

#### Legend

- I: Input
- O: Output
- H: High-level output
- L: Low-level output
- Z: High impedance
- P: Input or output depending on register setting
- K: Input pin is high impedance, output pin holds the state
- V: I/O buffer off, pullup MOS on

- Notes: 1. Depending on the clock mode (MD2 to MD0 setting)
2. 0 when DA output is enabled; otherwise Z.
3. K or P when the port function is used.
4. K or P when the port function is used. Z or O when the port function is not used depending on register setting.

5. K or P when the port function is used. I or O when the port function is not used depending on register setting.
6. Depending on register setting
7. I or O when the port function is used.
8. Input Schmitt buffers of IRQ[5:0] and ADTRG are on. Input Schmitt buffers of the other inputs (e.g. PTH, CTS2) that are shared with these pins are off.
9. O when DA output is enabled; otherwise depends on a register setting.
10. In the standby mode, Z or L depending on register setting.
11. In the standby mode, Z or H depending on register setting.

## B.2 Pin Specifications

Table B.2 shows the pin specifications.

**Table B.2 Pin Specifications**

| Pin                                                              | Number of Pins                                                                                                           |                                                                                                                             | I/O                | Function                                                                                    |

### B.3 Processing of Unused Pins

- When RTC is not used
  - EXTAL2: Pull up to ( $V_{cc}$ -RTC)
  - XTAL2: Leave unconnected
  - $V_{cc}$  – RTC: Power supply (1.9)
  - $V_{ss}$  – RTC: Power supply (0 V)
- When PLL1 is not used
  - CAP1: Leave unconnected
  - $V_{cc}$  – PLL1: Power supply (1.9)
  - $V_{ss}$  – PLL1: Power supply (0 V)
- When PLL2 is not used
  - CAP2: Leave unconnected
  - $V_{cc}$  – PLL2: Power supply (1.9 V)
  - $V_{ss}$  – PLL2: Power supply (0 V)
- When on-chip crystal oscillator is not used
  - XTAL: Leave unconnected
- When EXTAL pin is not used
  - EXTAL: Pull up to  $V_{cc}Q$  (3.3 V) or  $V_{ss}$
- When A/D converter is not used
  - AN[3:0]: Leave unconnected
  - $AV_{cc}$ : Power supply (3.3 V)
  - $AV_{ss}$ : Power supply (0 V)
- When hardware standby is not used
  - CA: Pull up to  $V_{cc}Q$

## B.4 Pin States in Access to Each Address Space

**Table B.3 Pin States (Normal Memory/Little Endian)**

| Pin                     | 8-Bit Bus Width |                           | 16-Bit Bus Width         |                              |                       |
|-------------------------|-----------------|---------------------------|--------------------------|------------------------------|-----------------------|
|                         |                 | Byte/Word/Longword Access | Byte Access (Address 2n) | Byte Access (Address 2n + 1) | Word/Longword Access  |
| CS6 to CS2, CS0         |                 | Enabled                   | Enabled                  | Enabled                      | Enabled               |
| RD                      | R               | Low                       | Low                      | Low                          | Low                   |
|                         | W               | High                      | High                     | High                         | High                  |
| RD/WR                   | R               | High                      | High                     | High                         | High                  |
|                         | W               | Low                       | Low                      | Low                          | Low                   |

Notes: 1. Disabled when WCR2 register wait setting is 0.

2. Unused data pins should be switched to the port function, or pulled up or down.

3. The behavior of the CE pin in the big endian is the same as that in the little endian.

C.      **Product Lineup**

| Model Marking  | Package                        |
|----------------|--------------------------------|
| HD6417706F133  | 176-pin plastic LQFP (FP-176C) |
| HD6417706BP133 | 208-pin TFBGA (TBP-208A)       |

## D. Package Dimensions

Figures D.1 and D.2 show the SH7706 package dimensions.
