1 Introduction

The MWCT1R24 is a Bluetooth® Low Energy ver. 4.2 compliant transceiver. It features an integral part of the 65-W consumer wireless power transfer system. Its assignment is to provide the communication link between the wireless power controller (MWCT1x23) on the power transmitter unit and the wireless power controller with integrated radio (MWPRx24) on the power receiver unit. The UART serves as the connection between the wireless power controller and the wireless power radio on the wireless power transmitter unit.

The wireless communication link represents proprietary system which is not opened to the end user.

4.3 Transceiver Functions

Receive

The receiver architecture is Zero IF (ZIF) where the received signal after passing through RF front end is down-converted to a baseband signal. The signal is filtered and amplified before it is fed to analog-to-digital converter. The digital signal is then decimated to a baseband clock frequency before it is digitally processed, demodulated and passed on to packet processing/link-layer processing.

Transmit

The transmitter transmits O-QPSK or GFSK/FSK modulation having power and channel selection adjustment per user application. After the channel of operation is determined, coarse and fine tuning is executed within the Frac-N PLL to engage signal lock. After signal lock is established, the modulated buffered signal is then routed to a multi-stage amplifier for transmission. The differential signals at the output of the PA (RF_P, RF_N) are converted to a single ended(SE) output signal by an on-chip balun.

6 System and Power Management

6.1 Power Management

The MWCT1R24 includes internal power management features that can be used to control the power usage. The power management of the MWCT1R24 includes power management controller (PMC) and a DC-DC converter which can operate in a buck, boost or bypass configuration. The PMC is designed such that the RF radio will remain

in state-retention while the core is in various stop modes. It can make sure the device can stay in low current consumption mode while the RF radio can wakeup quick enough for communication.

6.1.1 DC-DC Converter

The features of the DC-DC converter include the following:

- Single inductor, multiple outputs.
- Boost mode (pin selectable; CFG=GND).
- Buck mode (pin selectable; CFG=VDCDC_IN).
- Continuous or pulsed operation (hardware/software configurable).
- Power switch input to allow external control of power up, and to select bypass mode.
- Output signal to indicate power stable. Purpose is for the rest of the chip to be used as a POR.
- Scaled battery output voltage suitable for SAR ADC utilization.
- Internal oscillator for support when the reference oscillator is not present.
- 1.8 V output is capable of supplying the external device a maximum of 38.9 mA (VDD_1P8OUT = 1.8 V, VDCDC_IN = 3.0 V) and 20.9 mA (VDD_1P8OUT = 3.0 V, VDCDC_IN = 3.0 V), with MCU in RUN mode, peripherals are disabled.

6.2 Modes of Operation

The Arm Cortex-M0+ core in the MWCT1R24 has three primary modes of operation: Run, Wait, and Stop modes. For each run mode, there is a corresponding wait and stop mode. Wait modes are similar to Arm sleep modes. Stop modes are similar to Arm deep sleep modes. The very low power run (VLPR) operation mode can drastically reduce runtime power when the maximum bus frequency is not required to handle the application needs.

The WFI instruction invokes both wait and stop modes. The primary modes are augmented in a number of ways to provide lower power based on application needs.

6.2.1 Power modes

The power management controller (PMC) provides multiple power options to allow the user to optimize power consumption for the level of functionality needed.

Depending on the stop requirements of the user application, a variety of stop modes are available that provide state retention, partial power down or full power down of certain logic and/or memory. I/O states are held in all modes of operation. The following table compares the various power modes available.

For each run mode there is a corresponding wait and stop mode. Wait modes are similar to Arm sleep modes. Stop modes (VLPS, STOP) are similar to Arm sleep deep mode. The very low power run (VLPR) operating mode can drastically reduce runtime power when the maximum bus frequency is not required to handle the application needs.

The three primary modes of operation are run, wait and stop. The WFI instruction invokes either wait or stop depending on the SLEEPDEEP bit in Cortex-M0+ System Control Register. The primary modes are augmented in a number of ways to provide lower power based on application needs.

Table 8. Power modes (At 25 deg C)

Power mode	Description	CPU recovery method	Radio
Normal Run (all peripherals clock off)	Allows maximum performance of chip.	—	Radio can be active
Normal Wait - via WFI	Allows peripherals to function, while allowing CPU to go to sleep reducing power.	Interrupt	
Normal Stop - via WFI	Places chip in static state. Lowest power mode that retains all registers while maintaining LVD protection.	Interrupt	
PStop2 (Partial Stop 2)	Core and system clocks are gated. Bus clock remains active. Masters and slaves clocked by bus clock remain in Run or VLPRun mode. The clock generators in MCG and the on-chip regulator in the PMC also remain in Run or VLPRun mode.	Interrupt	
PStop1 (Partial Stop 1)	Core, system clocks and bus clock are gated. All bus masters and slaves enter Stop mode. The clock generators in MCG and the on-chip regulator in the PMC also remain in Run or VLPRun mode.	Interrupt	
VLPR (Very Low Power Run) (all peripherals off)	Reduced frequency (1MHz) Flash access mode, regulator in low power mode, LVD off. Internal oscillator can provide low power 4 MHz source for core. (Values @2MHz core/ 1MHz bus and flash, module off, execution from flash). Biasing is disabled when DC-DC is configured for continuous mode in VLPR/W	—	Radio operation is possible only when DC-DC is configured for continuous mode. ¹ However, there may be insufficient MIPS with a 4MHz MCU to support much in the way of radio operation.
VLPW (Very Low Power Wait) - via WFI (all peripherals off)	Similar to VLPR, with CPU in sleep to further reduce power. (Values @4MHz core/ 1MHz bus, module off) Biasing is disabled when DC-DC is configured for continuous mode in VLPR/W	Interrupt

VLLS0 (Very Low Leakage Stop0) with Brown-out Detection	VLLS0 is not supported with DC-DC The 32-byte system register file remains powered for customer-critical data. Disable all analog modules in PMC and retains I/O state and DGO state. LPO disabled, POR brown-out detection enabled, Pin interrupt only. Radio logic is power gated.	Wakeup Reset	Radio operation not supported. The Radio digital is power-gated in VLLS1/0
VLLS0 (Very Low Leakage Stop0) without Brown-out Detection	VLLS0 is not supported with DC-DC buck/boost configuration but is supported with bypass configuration The 32-byte system register file remains powered for customer-critical data. 1. Biasing is disabled, but the flash is in a low power mode for VLPx, so this configuration can realize some power savings over use of Run/Wait/Stop

If V_{IN} greater than V_{IO_MIN} ($= V_{SS}-0.3\text{ V}$) is observed, then there is no need to provide current limiting resistors at the pads. If this limit cannot be observed then a current limiting resistor is required. The negative DC injection current limiting resistor is calculated as $R = (V_{IO_MIN} - V_{IN})/|I_{ICIO}|$.
- Open drain outputs must be pulled to V_{DD} .

7.2.4 Power mode transition operating behaviors

All specifications except t_{POR} and VLLSx→RUN recovery times in the following table assume this clock configuration:

- CPU and system clocks = 48 MHz
- Bus and flash clock = 24 MHz
- FEI clock mode

POR and VLLSx→RUN recovery use FEI clock mode at the default CPU and system frequency of 21 MHz, and a bus and flash clock frequency of 10.5 MHz.

1. Normal boot (FTFA_FOPT[LPBOOT]=11). When the DC-DC converter is in bypass mode, TPOR will not meet the 300μs spec when 1) VDD_1P5 < 1.6V at 25°C and °C. 2) 1.5V ≤ VDD_1P5 ≤ 1.8V. For the bypass mode special case where VDD_1P5 = VDD_1P8, TPOR did not meet the 300μs maximum spec when the supply slew rate ≤ 100V/s.

Symbol	Description	Min.	Typ.	Max.	Unit	Notes

$t_{fll_acquire}$	FLL target frequency acquisition time	—	—	1	ms	8

1. This parameter is measured with the internal reference (slow clock) being used as a reference to the FLL (FEI clock mode).
2. The deviation is relative to the factory trimmed frequency at nominal V_{DD} and 25°C , f_{ints_ft} .
3. These typical values listed are with the slow internal reference clock (FEI) using factory trim and $DMX32 = 0$.
4. The resulting system clock frequencies must not exceed their maximum specified values. The DCO frequency deviation (Δf_{dco_t}) over voltage and temperature must be considered.
5. These typical values listed are with the slow internal reference clock (FEI) using factory trim and $DMX32 = 1$.
6. The resulting clock frequency must not exceed the maximum specified clock frequency of the device.
7. This specification is based on standard deviation (RMS) of period or frequency.
8. This specification applies to any time the FLL reference source or reference divider is changed, trim value is changed, $DMX32$ bit is changed, DRS bits are changed, or changing from FLL disabled (BLPE, BLPI) to FLL enabled (FEI, FEE, FBE, FBI). If a crystal/resonator is being used as the reference, this specification assumes it is already running.

7.5.3.2 Reference Oscillator Specification

The MWCT1R24 has been designed to meet targeted specifications with a +/-20 ppm frequency error over the life of the part, which includes the temperature, mechanical and aging effects.

The table below lists the recommended crystal specifications. Note that these are recommendations only and deviation may be allowed. However, deviations may result in degraded RF performance or possibly a failure to meet RF protocol certification standards. Designers must ensure that the crystal(s) they use will meet the requirements of their application.

Data hold time for I ² C bus devices	$t_{HD; DAT}$	0 ¹	3.45 ²	0 ³	0.9 ¹	μs
Data set-up time	$t_{SU; DAT}$	250 ⁴	—	100 ^{2, 5}	—	ns
Rise time of SDA and SCL signals	t_r	—	1000	$20 + 0.1C_b$ ⁶	300	ns
Fall time of SDA and SCL signals	t_f	—	300	$20 + 0.1C_b$ ⁵	300	ns
Set-up time for STOP condition	$t_{SU; STO}$	4	—	0.6	—	μs
Bus free time between STOP and START condition	t_{BUF}	4.7	—	1.3	—	μs
Pulse width of spikes that must be suppressed by the input filter	t_{SP}	N/A	N/A	0	50	ns

1. The master mode I²C deasserts ACK of an address byte simultaneously with the falling edge of SCL. If no slaves acknowledge this address byte, then a negative hold time can result, depending on the edge rates of the SDA and SCL lines.
2. The maximum $t_{HD; DAT}$ must be met only if the device does not stretch the LOW period (t_{LOW}) of the SCL signal.
3. Input signal Slew = 10 ns and Output Load = 50 pF.
4. Set-up time in slave-transmitter mode is 1 IP Bus clock period, if the TX FIFO is empty.
5. A Fast mode I²C bus device can be used in a Standard mode I²C bus system, but the requirement $t_{SU; DAT} \geq 250$ ns must then be met. This is automatically the case if the device does not stretch the LOW period of the SCL signal. If such

- a device does stretch the LOW period of the SCL signal, then it must output the next data bit to the SDA line $t_{rmax} + t_{SU}$; $t_{DAT} = 1000 + 250 = 1250$ ns (according to the Standard mode I²C bus specification) before the SCL line is released.
6. C_b = total capacitance of the one bus line in pF.

1. This is the steady state DC output power. It requires VDCDC_IN ≥ 1.7V in boost mode. Excessive transient current load from external device will cause 1P8V and 1P5 output voltage unregulated temporary.
2. This is the frequency that will be observed at LN and LP pins.
3. The voltage output level can be controlled by programming DCDC_VDD1P8CTRL_TRG field in DCDC_REG3.
4. The output current specification in both buck and boost modes represents the maximum current the DC-DC converter can deliver. The MWCT1R24 radio and MCU blocks current consumption is not excluded. Note that the maximum output power of the DC-DC converter is 125mW. The available supply current for external device depends on the energy consumed by the internal peripherals in MWCT1R24.
5. When using DC-DC in low power mode(pulsed mode), current load must be less than 0.5 mA.
6. The minimum VDD_1P5_boost is the maximum of either what is programmed using DCDC_VDD1P5CTRL_TRG_BOOST field in DCDC_REG3 or VDCDC_IN_boost + 0.05V. For example, if VDCDC_IN = 0.9V, minimum VDD_1P5 is as programmed in DCDC_VDD1P5CTRL_TRG_BOOST. If VDCDC_IN = 1.5V, minimum VDD_1P5 = 1.5 + 0.05V is 1.55V.
7. 1.8 V is the default value of the DC-DC 1.5 V output voltage in boost mode. The user can program DCDC_VDD1P5CTRL_TRG_BOOST field in register DCDC_REG3 to control 1.5 V output voltage level. For reliable radio operation, a voltage level of 1.425 V is required. VDD_1P5 must not be programmed higher than VDD_1P8.
8. 1.5 V is intended to supply power to MWCT1R24 only. It is not designed to supply power to an external device.
9. Turn on time is measured from the application of power (to DCDC_IN) to when the DCDC_REG0[DCDC_STS_DC_OK] bit is set. Code execution may begin before the DCDC_REG0[DCDC_STS_DC_OK] bit is set. Full device specification is not guaranteed until the bit sets.
10. In Buck mode, the maximum VDD_1P8 output is the minimum of either VDCDC_IN_BUCK minus 50 mV or 3.5 V. For example, if VDCDC_IN = 1.85V, maximum VDD_1P8 is 1.8V. If VDCDC_IN = 4.2V, maximum VDD_1P8 is 3V.
11. 1.5 V is the default value of DCDC VDD_1P5 in buck mode. The user can program DCDC_VDD1P5CTRL_TRG_BUCK field in register DCDC_REG3 to control 1P5 output voltage level. For Radio operation, minimum 1.425 V is required. VDD_1P5 must not be programmed higher than VDD_1P8.
