

**FEATURES**

- High Slew Rate ..... 10V/ $\mu$ s Min
- Fast Settling Time ..... 0.9 $\mu$ s to 0.1% Typ
- Low Input Offset Voltage Drift ..... 10 $\mu$ V/ $^{\circ}$ C Max
- Wide Bandwidth ..... 3.5MHz Min
- Temperature-Compensated Input Bias Currents
- Guaranteed Input Bias Current ..... 18nA Max (125 $^{\circ}$ C)
- Bias Current Specified Warmed-Up Over Temperature
- Low Input Noise Current ..... 0.01pA/ $\sqrt{Hz}$  Typ
- High Common-Mode Rejection Ratio ..... 86dB Min
- Pin Compatible With Standard Dual Pinouts
- 125 $^{\circ}$ C Temperature Tested DICE
- Models With MIL-STD-883 Class B Processing Available
- Available in Die Form

- For devices processed in total compliance to MIL-STD-883, add /883 after part number. Consult factory for 883 data sheet.
- † Burn-in is available on commercial and industrial temperature range parts in CerDIP, plastic DIP, and TO-can packages.

**GENERAL DESCRIPTION**

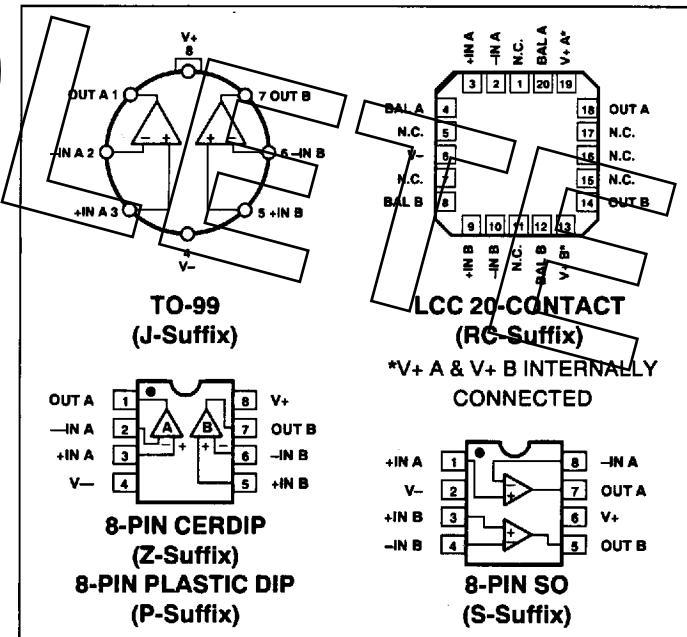

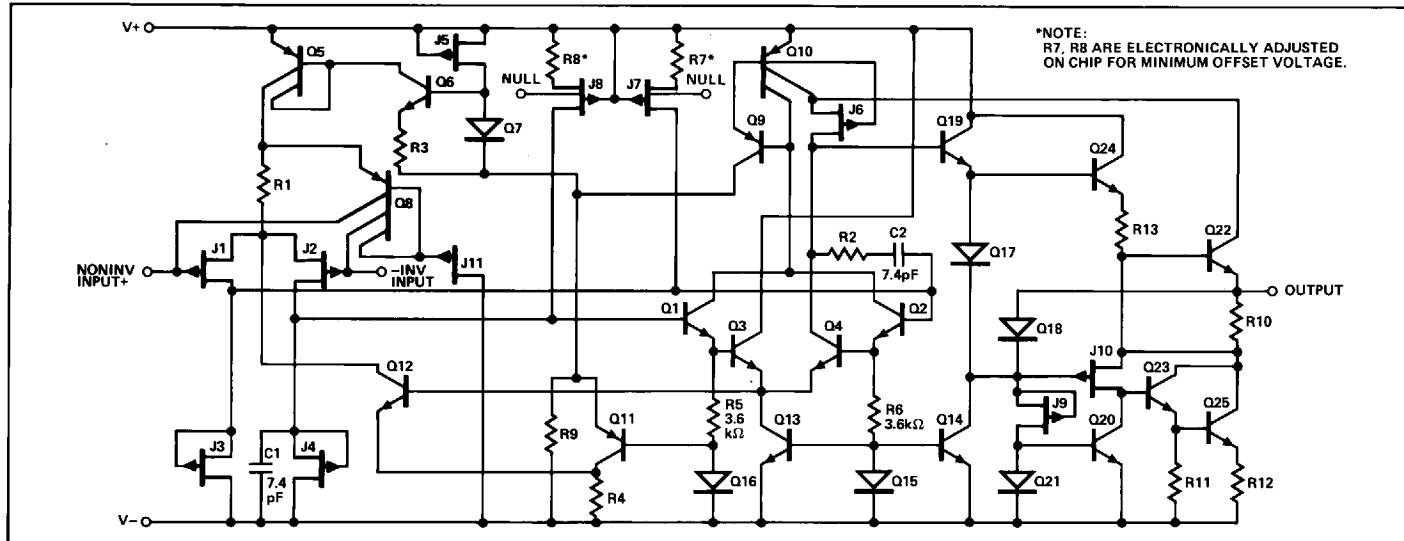

The OP-215 offers the proven JFET-input performance advantages of high speed and low input bias current with the

tracking and convenience advantages of a dual op-amp configuration.

Low input offset voltages, low input currents, and low drift are featured in these high-speed amplifiers.

On-chip zener-zap trimming is used to achieve low  $V_{os}$  while a bias-current compensation scheme gives a low input bias current at elevated temperatures. Thus the OP-215 features an input bias current of 18nA at 125 $^{\circ}$ C ambient (not junction) temperature which greatly extends the application usefulness of this device.

Applications include high-speed amplifiers for current output DACs, active filters, sample-and-hold buffers, and photocell

**NOTES:**

1. Input bias current is specified for two different conditions. The  $T_j = 25^\circ C$  specification is with the junction at ambient temperature; the Device Operating specification is with the device operating in a warmed-up condition at  $25^\circ C$  ambient. The warmed-up bias current value is correlated to the junction temperature value via the curves of  $I_B$  vs.  $T_j$  and  $I_B$  vs.  $T_A$ . PMI has a bias current compensation circuit which gives improved bias current and bias current over temperature vs. standard JFET input op amps.  $I_B$  and  $I_{OS}$  are measured at  $V_{CM} = 0$ .
2. Settling time is defined here for a unity gain inverter connection using  $2k\Omega$  resistors. It is the time required for the error voltage (the voltage at the inverting input pin on the amplifier) to settle to within a specified percent of its final value from the time a 10V step input is applied to the inverter. See settling time test circuit.
3. Sample tested.

### NOTES:

For 25°C characteristics of NT & GT devices, see N & G characteristics respectively.

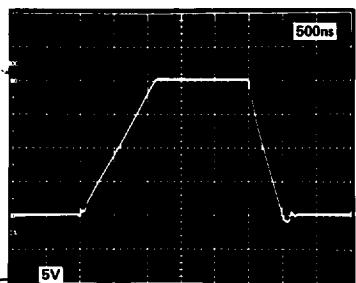

Electrical tests are performed at wafer probe to the limits shown. Due to variations in assembly methods and normal yield loss, yield after packaging is not guaranteed for standard product dice. Consult factory to negotiate specifications based on dice lot qualification through sample lot assembly and testing.

## INPUT OFFSET VOLTAGE NULLING

**BASIC CONNECTIONS****BURN-IN CIRCUIT****APPLICATIONS INFORMATION****DYNAMIC OPERATING CONSIDERATIONS**

As with most amplifiers, care should be taken with lead dress, component placement and supply decoupling in order to ensure stability. For example, resistors from the output to an input should be placed with the body close to the input to minimize "pick-up" and maximize the frequency of the feedback pole by minimizing the capacitance from the input to ground.

A feedback pole is created when the feedback around any amplifier is resistive. The parallel resistance and capacitance from the input of the device (usually the inverting input) to

AC ground sets the frequency of the pole. In many instances, the frequency of this pole is much greater than the expected 3dB frequency of the closed-loop gain and consequently there is negligible effect on stability margin. However, if the feedback pole is less than approximately six times the expected 3dB frequency, a lead capacitor should be placed from the output to the negative input of the op amp. The value of the added capacitor should be such that the RC time constant of this capacitor and the resistance it parallels is greater than, or equal to, the original feedback-pole time constant.
