| <b>Note:</b> Because this register is implemented as one physical register common to all Ports, the upstream Port's register (which is <b>reserved</b> ) has the same value as the downstream Ports' registers. However in the upstream Port, the ACS Extended Capability is excluded from the Linked List of PCI Express Extended Capabilities; therefore, the upstream Port's register is effectively hidden from system software, and the non-zero value has no significant consequence. |                                                                                                                               |            |       |                                    |         |

## 14.16 Device-Specific Registers (Offsets 530h – F8Ch)

This section details the Device-Specific registers located at offsets 530h through F8Ch. Device-Specific registers are unique to the PEX 8609 and not referenced in the *PCI Express Base r2.0*. [Table 14-29](#) defines the register map.

Other Device-Specific registers are detailed in [Section 14.14, “Device-Specific Registers \(Offsets 1C0h – 51Ch\).”](#)

**Note:** *It is recommended that these registers not be changed from their default values.*

**Table 14-29. Device-Specific Register Map  
(Offsets 530h – F8Ch)**

| For each Port, there are eight time slices to be divided amongst VC0 and VC1. A value of 0 indicates that VC0 has the “right of way,” and similarly, a value of 1 indicates that VC1 has the “right of way.” The default value, AAh, represents Round-Robin arbitration (equal access to each Port) for VC0 and VC1. |                                                                 |       |                                    |         |

## 14.16.2 Device-Specific Registers – Read Pacing (Offsets 544h – 554h)

**Caution:** *Source Queuing and Read Pacing should not be concurrently enabled. The two features are incompatible and doing so can result in Fatal errors.*

This section details the Device-Specific Read Pacing registers. Although the Read Pacing feature is supported on all Ports, its registers are implemented only on the upstream Port; otherwise, these registers are **reserved**. Table 14-31 defines the register map.

Read Pacing is described, in detail, in Section 9.6, “Read Pacing.”

**Table 14-31. Device-Specific Read Pacing Register Map (Upstream Port, and also the NT Port Virtual Interface if the NT Port is a Legacy NT Port)**

This Counter specifies the maximum DWord of Memory Read Requests that can be outstanding for a x1 Port. Default value of 100h programs the threshold to 1 KB. | Upstream   | RW    | Yes                                | 100h    |

## 14.16.4 Device-Specific Registers – General-Purpose Input/Output (Offsets 62Ch – 65Ch)

This section details the Device-Specific General-Purpose Input/Output (GPIO) Configuration, Status, and Control registers. [Table 14-34](#) defines the register map.

**Table 14-34. Device-Specific GPIO Register Map

## 14.16.5 Device-Specific Registers – Ingress Control and Port Enable (Offsets 660h – 67Ch)

This section details the Device-Specific Ingress Control and Port Enable registers, which also include the **Negotiated Link Width**, **Port Cut-Thru Enable Status**, and **Ingress PLL RAM ECC 1-Bit Counter** registers. [Table 14-35](#) defines the register map.

**Table 14-35. Device-Specific Ingress Control and Port Enable Register Map**

### 14.16.7 Device-Specific Registers – Base Address Shadow (Offsets 6C0h – 73Ch)

This section details the Device-Specific Base Address Shadow registers, which are a shadow copy of the two Type 1 Configuration Base Address registers (**BAR0** and **BAR1**) for each PEX 8609 Port. [Table 14-38](#) defines the register map.

**Table 14-38. Device-Specific BAR Shadow Register Map (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port)**

## 14.16.8 Device-Specific Registers – Virtual Channel Resource Control Shadow, DMA BAR, and DMA Read and Write Latency (Offsets 740h – 83Ch)

This section details the Device-Specific Virtual Channel (VC) Resource Control Shadow registers, for each Port (which shadow the VC0 and VC1 registers at offsets [15Ch](#) and [168h](#), respectively), as well as DMA BAR, and DMA Read and Write Latency registers. [Table 14-39](#) defines the register map.

**Table 14-39. Device-Specific VC Resource Control Shadow, DMA BAR, and DMA Read and Write Latency Register Map (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port)**

Updates when a de-allocation for DMA Writes is received. If the current Write Latency is less than the register value, the current Write Latency becomes the new Minimum Write Latency. The Counter saturates at FFFFh and does not roll over to 0000h.    | RW1C | No                                 | FFFFh   |
| 31:16                                                                                                               | <b>DMA Maximum Write Latency</b><br>DMA Write Latency Counter. Updates when a de-allocation for DMA Writes is received. If the current Write Latency is greater than the register value, the current Write Latency becomes the new Maximum Write Latency. The Counter saturates at FFFFh and does not roll over to 0000h. | RW1C | No                                 | 0000h   |

## Device-Specific Registers – Ingress Credit Handler Port Pool (Offsets 940h – 94Ch)

This section details the Device-Specific Ingress Credit Handler (INCH) Port Pool registers. [Table 14-40](#) defines the register map.

The original intent for the INCH Port Pool registers was to provide another level of reservation of the Common Pool credits. These registers are essentially redundant to what is accomplished by changing the values of the **INCH Threshold** registers. (Refer to [Section 14.16.13.](#))

Consider the INCH Port Pool registers to be *reserved* and only change the credit Settings, using the INCH Threshold registers. Do not change the INCH Port Pool registers from their default values, unless directed otherwise by PLX Technical Support.

Refer to [Section 9.3, “Ingress Resources,”](#) and its subsections, for further details regarding credits and credit allocation.

#### 14.16.12 Device-Specific Registers – ACS Extended Capability (Offsets 980h – 9FCh)

This section details the Device-Specific ACS Extended Capability registers. The registers in this structure are shadow copies of the Port 0 registers located at offsets 524h and 528h, for each Port. Table 14-43 defines the register map.

**Table 14-43. Device-Specific ACS Extended Capability Register Map (Port 0)**

### 14.16.13 Device-Specific Registers – Ingress Credit Handler Threshold (Offsets A00h – B7Ch)

This section details the Device-Specific Ingress Credit Handler (INCH) Threshold registers. **Changing credit values from default register values must be done carefully; otherwise the PEX 8609 will not properly function.** Refer to [Section 9.3, “Ingress Resources,”](#) and its subsections, for detailed information regarding rules associated with changing the **INCH Threshold** registers. [Table 14-44](#) defines the register map.

**Table 14-44. Device-Specific INCH Threshold Register Map  
(Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port)**

| Non-Posted credits are used for VC1 Memory Read, I/O Read, I/O Write, Configuration Read, and Configuration Write transactions. Port x is Ports 0, 1, and 4 through 9 for register offsets A10h, A28h, A70h, A88h, AA0h, AB8h, AD0h, and AE8h, respectively. (Refer to <a href="#">Table 14-44</a> .) |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |       |                                    |         |
| 8:0                                                                                                                                                                                                                                                                                                   | <b>Non-Posted Payload Credit</b><br>The Non-Posted Payload is stored with the Non-Posted Header; therefore Non-Posted Payload credit is always available. Because of this, the PEX 8609 hardwires this field to 000h (infinite credits).                                                                                                                                                                                                                                                                                                                                                                                                                                       | RsvdP | Yes                                | 000h    |
| 15:9                                                                                                                                                                                                                                                                                                  | <b>Non-Posted Header Credit</b><br>Default advertised Non-Posted Header credit. Actual value is dependent upon Link width and Port configuration.<br>Bit resolution is 1 for 1. Each increment provides 1 Non-Posted Header credit ( <i>for example</i> , Ah = 10 Non-Posted Header credits). Each credit means that storage is reserved for the entire Header of a Non-Posted TLP. The PEX 8609 hardwires this field to 00h (infinite credits).<br><i><b>Note:</b> The default initial credit is infinite. If VC1 is enabled, the user must calculate and program the needed optimal VC1 initial credit values. These values should be programmed, using a serial EEPROM.</i> | RWS   | Yes                                | 00h     |

| <p>The default value of this register, when combined with the <b>Post-Cursor Emphasis Level 0</b> register (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offset BA8h) default value, provides -3.5 dB of de-emphasis. However, it is also a Status register with provisional read-back data.</p> <p>The power-up reset default values of this register correspond to -3.5 dB drive levels, and can be overwritten by serial EEPROM and/or Configuration Space register transactions. However, when read back, the returned data always represents the <b>current value being applied to the Lane</b>. That is because the Write Data value is written into a holding register for the -3.5 dB value, but cannot be directly read from the register. The Read Data value is always sourced from an active Drive register that is loaded dynamically upon de-emphasis changes.</p> <p><b>Note:</b> Refer to <a href="#">Section 21.7, “Transmit Drive Characteristics,”</a> for a complete breakout of the default values, and their relationship with the <b>Post-Cursor Emphasis Level 0</b> register.</p> |                                                                                                                                                                                                                                                                                                                                                                                                           |       |                                    |                                                            |

| <p>The default value of this register, when combined with the <b>Post-Cursor Emphasis Level 2</b> register (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offset BB0h) default value, provides -3.5 dB of de-emphasis. However, it is also a Status register with provisional read-back data.</p> <p>The power-up reset default values of this register correspond to -3.5 dB drive levels, and can be overwritten by serial EEPROM and/or Configuration Space register transactions. However, when read back, the returned data always represents the <b>current value being applied to the Lane</b>. That is because the Write Data value is written into a holding register for the -3.5 dB value, but cannot be directly read from the register. The Read Data value is always sourced from an active Drive register that is loaded dynamically upon de-emphasis changes.</p> <p><b>Note:</b> Refer to <a href="#">Section 21.7, “Transmit Drive Characteristics,”</a> for a complete breakout of the default values, and their relationship with the <b>Post-Cursor Emphasis Level 2</b> register.</p> |                                                                                                                                                                                                                                                                                                                                                                                                           |       |                                    |                                                            |

| <p>The default value of this register, when combined with the <b>SerDes Drive Level 0</b> register (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offset <b>B98h</b>) default value, provides -3.5 dB of de-emphasis.</p> <p>The power-up value can be overwritten by serial EEPROM and/or Configuration Space register transactions. However, when read back, the returned data always represents the <b>current value being applied to the Lane</b>. That is because the Write Data value is written into a holding register for the -3.5 dB value, but cannot be directly read from the register. The Read Data value is always sourced from an active Drive register that is loaded dynamically upon de-emphasis changes.</p> <p><b>Note:</b> Refer to <a href="#">Section 21.7, “Transmit Drive Characteristics,”</a> for a complete breakout of the default values, and their relationship with the <b>SerDes Drive Level 0</b> register.</p> |                                                                                                                                                                                                                                                                                                                                                                                                                                          |       |                                    |                                                            |

| <p>The default value of this register, when combined with the <a href="#">SerDes Drive Level 2</a> register (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offset <a href="#">BA0h</a>) default value, provides -3.5 dB of de-emphasis.</p> <p>The power-up value can be overwritten by serial EEPROM and/or Configuration Space register transactions. However, when read back, the returned data always represents the <i>current value being applied to the Lane</i>. That is because the Write Data value is written into a holding register for the -3.5 dB value, but cannot be directly read from the register. The Read Data value is always sourced from an active Drive register that is loaded dynamically upon de-emphasis changes.</p> <p><b>Note:</b> Refer to <a href="#">Section 21.7, “Transmit Drive Characteristics,”</a> for a complete breakout of the default values, and their relationship with the <a href="#">SerDes Drive Level 2</a> register.</p> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |       |                                    |                                                            |

14.16.16 Device-Specific Registers – Physical Layer (Offsets E40h – EFCh)

This section details the Device-Specific Physical Layer (PHY) registers located at offsets E40h through EFCh. Table 14-47 defines the register map.

Other Device-Specific PHY registers are detailed in:

- Section 14.14.2, “Device-Specific Registers – Physical Layer (Offsets 200h – 25Ch)”
- Section 14.16.14, “Device-Specific Registers – Physical Layer (Offsets B80h – C30h)”

### 14.16.18 Device-Specific Registers – Error Reporting (Offsets F40h – F4Ch)

This section details the Device-Specific Error Reporting registers, which shadow the corresponding **Device Control** register Error Reporting-related bits (offset 70h[2:0]), for each Port. Table 14-49 defines the register map.

**Table 14-49. Device-Specific Error Reporting Register Map (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port)**

|                                             |                         |                                       |      |

## 14.16.19 Device-Specific Registers – ARI Capability (Offsets F50h – F8Ch)

This section details the Device-Specific ARI Capability registers, which shadow ARI-related bits at offsets 8Ch[5] and 90h[5], for each Port. Table 14-50 defines the register map.

**Table 14-50. Device-Specific ARI Capability Register Map (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port)**

| 31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 | 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0 |             |

## Chapter 15 Non-Transparent Bridging – NT Mode Only

### 15.1 Introduction

**Note:** Check the latest design guides, application notes and errata list for Non-Transparent (NT) usage.

The PEX 8609 supports Non-Transparent (NT) bridge functionality (NT mode), which is used to implement High-Availability systems or Intelligent I/O modules using PCI Express technology. The following discusses the basic NT bridging concept, as it applies to a PCI Express system.

NT bridges allow systems to isolate Address spaces, by appearing as an endpoint to the Host. The NT bridge exposes a Type 0 Configuration Space register (CSR) Header and forwards transactions from one domain to the other, using address translation. The NT bridge is used to connect two independent address/Host domains. The NT bridge includes **Doorbell** registers, for transmitting interrupts from one side of the bridge to the other. The bridge also includes **Scratchpad** registers, accessible from both domains for inter-Host communication. The PEX 8609, with a single Port configured to operate in NT mode, supports the **Intelligent Adapter Mode** system model. NT mode is enabled/disabled by the **STRAP\_NT\_ENABLE#** input.

The following are PEX 8609 Non-Transparent Bridging (NTB) key elements:

- [Device Type Identification](#)
- [NT Port Features](#)
- [Intelligent Adapter Mode](#)
- [NT Port Reset](#)
- [NT Port Memory-Mapped Base Address Registers](#)
- [Doorbell Registers](#)
- [Scratchpad Registers](#)
- [NT Base Address Registers](#)
- [Address Translation](#)

#### 15.1.1 Device Type Identification

Devices identify themselves by way of the Conventional PCI Configuration Space register (CSR) Header **PCI Class Code** register. A Transparent PCI-to-PCI bridge identifies itself as a **PCI Class Code 060400h**. An NT bridge identifies itself as “Other Bridge,” **068000h**, with a Type 0 Header, which is consistent with the use of other NT bridges available in the industry.

The **PCI Express Capability** register includes a **Device/Port Type** field (offset 68h[23:20]). In this register, a Transparent bridge/switch Port identifies itself as an *upstream or downstream Port*, while an NT bridge/switch NT Port identifies itself as a *PCI Express endpoint*.

## 15.1.2 NT Port Features

- Maps PEX 8609 Configuration registers into either 32- or 64-bit Memory space
- Base Address registers (BARs)
  - Implements four 32-bit, two 32-bit and one 64-bit, or two 64-bit BARs
  - Supports BAR Size programming, through the **BARx Setup** register(s)
  - Allows BARs to be individually disabled, including Memory-Mapped BARs
- Supports [Direct Address Translation](#)
  - 32-to-32-bit address conversion
  - 32-to-64-bit address conversion
  - 64-to-32-bit address conversion
  - 64-to-64-bit address conversion
  - Requester ID (Bus Number, Device Number, and Function Number) conversion across the NT bridge
- **Doorbell** registers
- **Scratchpad** registers
- Supports Requester ID and Completion ID translation
- NT Port Link Interface *DL\_Active* state change generates interrupt to Local Host
- Supports Cursor mechanism
- Supports Expansion ROM on either NT Port interface
- Supports End-to-end Cyclic Redundancy Check (ECRC)
- Provides ability to Clear *No Snoop* Transaction Layer Packet (TLP) attribute (if enabled)
- Programmable upstream Port and NT Port for the enabling of High Availability systems (Failover and Redundant systems)
- Brings down the NT Port Link when the Local Host domain is down (if enabled)
- Supports the Fencing mechanism
- Signals Device-Specific interrupt to the Local Host when the NT Port Link Interface detects TLP errors
- Signals Device-Specific interrupt to the Local Host when the NT Port Link Interface receives Error Messages (Safety bit-controllable)
- Disables NT Port Link Interface Hot Reset effect (enabled, by default)
- Supports Configuration Space access control
- Option to appear behind a PCI-to-PCI bridge (refer to [STRAP\\_NT\\_P2P\\_EN#](#) ball description)

### 15.1.3 Intelligent Adapter Mode

The use of NT bridges in PCI systems is well-established for supporting intelligent adapters in enterprise and multi-Host systems. The same concept is used in PCI Express bridges and switches.

In [Figure 15-1](#), there are two Type 0 CSR Headers in the NT bridge. The one nearer the internal virtual PCI Bus is referred to as the *Virtual Interface*. The one nearer the PCI Express Link is referred to as the *Link Interface*.

In Intelligent Adapter mode, the NT Port Link Interface is connected to the System Host domain. The System Host manages only the NT Port Link Interface Type 0 function. The Local Host manages all PEX 8609 Transparent Port Type 1 and NT Port Virtual Interface Type 0 functions. Cross-domain traffic is routed through an Address Translation mechanism. (Refer to [Section 15.1.9](#).)

**Figure 15-1. Intelligent Adapter Software Model**

## 15.1.4 NT Port Reset

The section discusses NT mode exceptions and enhancements to Transparent mode PCI Express (standard) reset behavior.

### 15.1.4.1 Fundamental Reset (PEX\_PERST#)

[PEX\\_PERST#](#) resets all PEX 8609 states, including NT Port states. This reset initializes all Sticky bits and Configuration registers in Virtual and Link spaces to default values.

### 15.1.4.2 Intelligent Adapter Mode NT Port Reset

When the Transparent upstream Port receives a Hot Reset or enters the *DL\_Down* state, the PEX 8609, by default, propagates the in-band reset to all Transparent downstream Ports and connected downstream devices (to reset the downstream hierarchy), then resets the internal switch fabric and the NT Port Virtual Interface. There is no reset propagation to the NT Port Link Interface, and the Link-side remains intact.

When the NT Port Link Interface receives a Hot Reset or enters the *DL\_Down* state, the NT Port Link Interface registers are reset, by default. This Soft Reset does not reset the Transparent Ports nor the NT Port Virtual Interface. Instead, when the NT Port Link Interface receives a Hot Reset (or enters the *DL\_Down* state), the [PEX\\_NT\\_RESET#](#) output is asserted Low for 1  $\mu$ s. The system can use this signal to trigger a reset of the entire Local subsystem.

The PEX 8609 supports an option that allows these Hot Reset conditions at its Transparent upstream Port and NT Port Link Interface to be masked (disabled) for all Ports, including the NT Port, by Setting the **Debug Control** register *Upstream Port and NT-Link DL\_Down Reset Propagation Disable* bit (NT Port Virtual Interface if Port 0 is a Legacy NT Port, offset 1DCh[20]).

When software writes to the PEX 8609 Transparent upstream Port's **Bridge Control** register *Secondary Bus Reset* bit (offset 3Ch[22]), the resulting *Secondary Bus Reset* is (as above) propagated to all PEX 8609 Transparent downstream Ports, and the Port states and NT Port Virtual Interface states are reset.

### 15.1.5 NT Port Memory-Mapped Base Address Registers

The NT Port Virtual and Link Interfaces individually claim 128 KB of memory, using **BAR0** and **BAR1**. The 128-KB space contains the CSRs for all PEX 8609 Ports. **BAR0** and **BAR1** can be programmed as one of the following:

- 32-bit BAR (**BAR1** is *reserved*; default mode)
- 64-bit BAR, by programming the Configuration **BAR0/1 Setup** register (the NT Port Virtual Interface offset is [D0h](#); the NT Port Link Interface offset is [E4h](#))
- **BAR0** and **BAR1** can be completely disabled

[Figure 15-2](#) provides a memory-mapped view of the PEX 8609 CSRs. This view is the same from the upstream Port, NT Port Virtual Interface, or NT Port Link Interface.

Figure 15-2. NT Mode Configuration Register Mapping to Memory-Mapped BAR

## 15.1.6 Doorbell Registers

**Doorbell** registers are used to signal interrupts from one side of the NT bridge to the other. This section describes a typical set of Doorbell Control registers.

A 16-bit software-controlled Interrupt Request register and associated 16-bit Mask register are implemented for the NT Port Virtual and Link Interfaces. The Doorbell mechanisms consist of the following registers:

- **Virtual Interface IRQ Set**
- **Virtual Interface IRQ Clear**
- **Virtual Interface IRQ Mask Set**
- **Virtual Interface IRQ Mask Clear**
- **Link Interface IRQ Set**
- **Link Interface IRQ Clear**
- **Link Interface IRQ Mask Set**
- **Link Interface IRQ Mask Clear**

The Virtual Interface IRQ is for interrupts that exit the NT Port Virtual Interface. An interrupt is asserted on the NT Port Virtual Interface when one or more of the **Virtual Interface IRQ Set** register bits are Set by the NT Port Link Interface and their corresponding **Virtual Interface IRQ Mask Set** register bits are Cleared. An interrupt is de-asserted on the NT Port Virtual Interface when one or more of the **Virtual Interface IRQ Clear** register bits are Set from the NT Port Virtual Interface and their corresponding **Virtual Interface IRQ Mask Clear** register bits are Cleared. The interrupt is de-asserted when all Set bits are masked or Cleared.

The Link Interface IRQ is for interrupts that exit the NT Port Link Interface. An interrupt is asserted on the NT Port Link Interface when one or more of the **Link Interface IRQ Set** register bits are Set by the NT Port Virtual Interface and their corresponding **Link Interface IRQ Mask Set** register bits are Cleared. An interrupt is de-asserted on the NT Port Link Interface when one or more of the **Link Interface IRQ Clear** register bits are Set from the NT Port Link Interface and their corresponding **Link Interface IRQ Mask Clear** register bits are Cleared. The interrupt is de-asserted when all Set bits are masked or Cleared.

Because Memory Requests can access both sets of NT-Virtual and NT-Link Doorbell registers, software in either domain can generate Doorbell interrupts to both domains.

Internally, the **Set IRQ** and **Clear IRQ** registers are the same register. One location is used to Set bits and the other is used to Clear bits. The status can be read from either register.

In a PCI Express switch, interrupt state transitions (from Setting to Clearing, or vice versa) result in packets being transmitted upstream on the appropriate side of the bridge, when INTx are enabled (**PCI Command** register *Interrupt Disable* bit, offset 04h[10], is Cleared). Standard PCI Express Capability structures allow these interrupts to be configured as MSIs or INTx. When MSIs are enabled (**MSI Control** register *MSI Enable* bit, offset 48h[16], is Set), packets are transmitted only when interrupts transition from Clear IRQ to Set IRQ.

NT Port Doorbell interrupts can optionally use the **PEX\_INTA#** output for interrupt signaling, instead of the INTx or MSI signaling mechanisms. PEX\_INTA# output can be enabled for NT Port Doorbell interrupts, by Setting the **ECC Error Check Disable** register *Enable PEX\_INTA# Interrupt Output(s) for NT-Virtual Doorbell-Generated Interrupts* bit (NT Port Virtual Interface, or Port 0 if Port 0 is the NT Port, offset 1C8h[7]).

The PEX 8609 Virtual interrupts are de-asserted when the NT Port goes to the *DL\_Down* state.

## 15.1.7 Scratchpad Registers

**Scratchpad** registers are readable and writable from both sides of the NT bridge, providing a generic means for inter-Host communication. A block of eight registers are provided, accessible in Memory space from the NT Port Virtual and Link Interfaces. These registers pass Control and Status information between Virtual and Link Interface devices or they can be generic RW registers. Reading from or writing to **Scratchpad** registers does not cause interrupts to assert – **Doorbell** registers are used for that purpose. **Scratchpad** registers are reset only by a Fundamental Reset ([PEX\\_PERST#](#)).

The NT bridge uses the Conventional PCI set of BARs in its Type 0 CSR Header to define Address ranges into the Memory space on the other side of the bridge. BARs define resource Address ranges that allow transaction forwarding to the opposite (other side) interface.

## 15.1.8 NT Base Address Registers

There are two sets of NT Base Address registers (BARs) – one each for the NT Port Virtual and Link Interfaces. Each BAR has its own **Setup** and **Address Translation** register:

- **BARx Setup** registers enable/disable the BAR and define the window size and type. Program the **BARx Setup** registers prior to allowing configuration software to assign a resource for these BARs. (Discussed further in [Section 15.1.8.1](#).)
- **Memory BARx Address Translation** registers allow for an address change on the upper bits (up to the size of the space). Program the **Memory BARx Address Translation** registers, before generating traffic across the NT Port. This programming is typically performed by information downloaded from I<sup>2</sup>C, software, and/or an optional serial EEPROM (if present) on the destination side. The source side does not need to know what the Address Translation is.
- The address could change size. *For example*, the PEX 8609 NT Port allows a 32-bit device to communicate to a 64-bit device, and vice versa. (The same is true when the addresses are the same size, as well – a 32-bit device can communicate with a 32-bit device, and a 64-bit can communicate with a 64-bit device.)

### 15.1.8.1 NT BARx Setup Registers

PCI defines Base Address Registers (BARs) for a PCI device to claim Address space. For the PEX 8609, **BAR0** and **BAR1** provide Memory-Mapped access to the CSRs, while **BAR2**, **BAR3**, **BAR4**, and **BAR5** provide programmable window sizes to the other side of the NTB.

The **BARx Setup** registers are used to program the window size of each BAR. [Table 15-1](#) briefly describes each NT Port BAR. **BAR2**, **BAR3**, **BAR4**, and **BAR5** can be configured for accessing the Address space across the NT Port Virtual and Link Interfaces.

Each **BARx Setup** register defines the memory window size that is to be assigned by a system enumerator (*that is*, BIOS and/or firmware). *For example*, if the window size must be 1 MB, Memory space, and cacheable region, the **BARx Setup** register in 32-bit space will be FFF0\_0008h (FFF0\_0000h indicates the 1-MB space Request, bit 3 is the cacheable region, and bit 0 must be Memory space).

In most cases, the **BARx Setup** registers are programmed using an optional serial EEPROM (if present), before the BIOS or firmware allocates the resources (because resource enumeration is done before the system software can access these devices).

Table 15-1. NT Port Virtual and Link Interface BARs

| BAR         | NT Port Virtual Interface Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | NT Port Link Interface Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <b>BAR5</b> | Configured by the <b>NT Port Virtual Interface Memory BAR4/5 Setup</b> register. <b>BAR5</b> can be implemented as a 32-bit BAR or upper half of a 64-bit BAR, by combining it with <b>BAR4</b> ( <b>BAR4/5</b> ). <b>BAR5</b> uses Direct Address Translation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Configured by the <b>NT Port Link Interface Memory BAR4/5 Setup</b> register. <b>BAR5</b> can be implemented as a 32-bit BAR or upper half of a 64-bit BAR, by combining it with <b>BAR4</b> ( <b>BAR4/5</b> ). <b>BAR5</b> uses Direct Address Translation.                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## 15.1.9 Address Translation

The Transparent bridge uses **Base** and **Limit** registers in I/O space, Non-Prefetchable Memory space, and Prefetchable Memory space to map transactions downstream, across the bridge. All downstream devices must be mapped in contiguous address regions, such that a single Address range in each space is sufficient. Upstream mapping is done by way of inverse decode, relative to the same registers. A Transparent bridge does not translate the addresses of forwarded transactions/packets.

In multi-domain systems, each Host domain has its own Address space, that is different from that of other Host domain(s). Hence, any transaction crossing the inter-domain boundary, by way of an NTB or other means, must support address, as well as Requester ID, translations.

Before a transaction (PCI Express packet) can go through the NT bridge (either from the Virtual-side to Link-side, or from Link-side to Virtual-side) in an inter-domain system, one or more sets of Memory resources must be assigned to the NT bridge. To request this resource from the system enumerator (BIOS and/or firmware), the NT bridge must be programmed with the **BARx Setup** register(s). (Refer to [Section 15.1.8.1](#).) The **BARx Setup** register(s) requests the window space size, memory type, 32- or 64-bit space, prefetchable or non-prefetchable area, using one 32-bit register for 32-bit Address space or the two 32-bit registers (**BAR2/3** or **BAR4/5**) for 64-bit Address space. In return, the system enumerator assigns resources to the NT bridge in **BAR0** through **BAR5**. Any transactions that target **BAR2** through **BAR5** on the NT Port Link Interface result in a transaction across the NT bridge, to the secondary address domain.

Similarly, in NT PCI-to-PCI Bridge mode, the NT PCI-to-PCI bridge must be enumerated to accommodate the resources assigned to the NT endpoint, to allow packets to logically traverse the bridge. Its Device Number (on the Internal Virtual PCI Bus) value is the NT Port Number. Device enumeration minimally includes the **PCI Command**, **Bus Number**, and **Memory Base and Limit** and/or **Prefetchable Memory Base and Limit** registers (offsets 04h, 18h, and 20h, and/or 24h). The Internal NT Virtual Bus (connecting the NT PCI-to-PCI secondary interface and NT endpoint) can be assigned any available Bus Number within the upstream Port's range of Subordinate Bus Numbers.

In addition, the Lookup Table (LUT) register(s) and **Memory BARx Address Translation** register(s) must be programmed. The LUTs are the Requester ID (Bus Number, Device Number, and Function Number) with the ability to disable features that allow Requester's transaction go through the NT bridge (if enabled). This adds security to the NT bridge, limiting the devices that can generate transactions across the NT bridge. LUTs also play a crucial role, because the Requester ID is also used to complete PCI Express Read Requests – during the PCI Express Read Request to the other domain side, the NT bridge uses its own Requester ID to translate the original PCI Read Request, and when the Completion returns, the NT bridge uses the original Requester ID to complete the transaction.

The Address Translation is used to re-direct the address of the PCI Express packet to a programmer-reserved area (instead of using the same address for both Host domains). Hence, any transaction targeting **BAR2** through **BAR5** can be translated (re-mapped) on the other side of the NT bridge while maintaining the offsets. These Translation registers can be changed during runtime, as long as there are no pending transactions.

The PEX 8609 NT Port Virtual and Link Interfaces support [Direct Address Translation](#), described in the following section.

### 15.1.9.1 Direct Address Translation

The **BAR<sub>x</sub> Setup** registers define a mask that splits the address into an upper *Base* field and a lower *Offset* field. Translation then consists of replacing, under the maskable portion of the **BAR<sub>x</sub> Setup** register, the Address Base register bits with the corresponding Address Translation register bits. Accordingly, the Address Translation register value must be a multiple of the corresponding BAR size. [Figure 15-3](#) illustrates Direct Address Translation.

The device(s) on the originating Host domain can communicate to a single device or multiple devices mapped to consecutive Memory Address space on the target Host domain, by using the Direct Address Translation mechanism. [Figure 15-4](#) illustrates the entire Address map, claimed by the NT Port, mapped into the single target device. [Figure 15-5](#) illustrates the entire Address map claimed by the NT Port, mapped into multiple target devices. Multiple devices must be in contiguous Memory Address ranges.

**Figure 15-3. Direct Address Translation**

**Figure 15-4. NT Port Mapped into Single Target Device**

**Figure 15-5. NT Port Mapped into Multiple Target Devices**

**Address Translation Example**

Assume the following:

1. NT Port Virtual Interface **BAR2** claims 128-KB Memory space (**BAR2 Setup** register = FFFE\_0000h).
2. Configuration software assigns the 5F00\_0000h address value to NT Port Virtual Interface **BAR2** and it is within the Transparent upstream Port Memory window.
3. Device driver software programs the **BAR2** Address Translation register to 2750\_0000h.

The PEX 8609 receives a transaction to the NT Port Virtual Interface, with address 5F00\_0080h. The received transaction address is hitting the NT Port Virtual Interface **BAR2**. The PEX 8609 claims the transaction and executes the address translation described in [Figure 15-6](#).

**Figure 15-6. Address Translation Example**

## 15.2 NT PCI-to-PCI Bridge Mode

The PEX 8609 provides an option to insert a PCI-to-PCI bridge (NT PCI-to-PCI bridge) between the NT Port Virtual Interface and internal virtual PCI Bus. Without the NT PCI-to-PCI bridge, the NT Port is parallel to other Transparent downstream bridges within the device hierarchy. This mode is referred to as *Legacy NT mode*. (Refer to [Figure 15-7](#).) With the NT PCI-to-PCI bridge, the NT Port Virtual Interface is connected under one of the downstream bridges. (Refer to [Figure 15-8](#).)

The NT PCI-to-PCI bridge is not connected to a physical Link; therefore, there are some minor differences in the Configuration registers, particularly in some Link control functionality. Insertion of the NT PCI-to-PCI bridge does not affect packet latency, and is controlled by the `STRAP_NT_P2P_EN#` input, when NT mode is enabled.

**Figure 15-7. Legacy NT Mode (STRAP\_NT\_P2P\_EN#=H)**

**Figure 15-8. NT PCI-to-PCI Bridge Mode (STRAP\_NT\_P2P\_EN#=L)**

## 15.3 Requester ID Translation

Configuration, Message, and Completion transactions are ID-routed instead of address-routed. Of these, the NT Port forwards only the Completion transaction between the two Host domains. PCI Express switches and bridges use the Requester ID (defined in the Completion TLP Header) to route these packets.

The Requester ID consists of the following:

- Requester's PCI Bus Number
- Device Number
- Function Number

The Completer ID consists of the following:

- Completer's PCI Bus Number
- Device Number
- Function Number

**Note:** The PCI Bus Number is unique for each Host domain.

Figure 15-9 illustrates the Memory Request TLP Header format. Figure 15-10 illustrates the Completion TLP Header format.

**Figure 15-9. Memory Request TLP Header Format**

### 15.3.1 Transaction Sequence

*To implement a transaction sequence:*

1. Requester inserts ID information into the Memory Read TLP that it generates on the initiating Host domain.
2. Switches and bridges between the transaction initiator and PEX 8609 NT Port route this Memory Read TLP, based upon the address.
3. NT Port replaces the Memory Read TLP Requester ID with its ID, and conducts the address translation before it forwards this Requester ID-translated TLP to the target Host domain, because the NT Port is the transaction initiator in the target Host domain.
4. Switches and bridges between the PEX 8609 NT Port and target device route this Memory Read TLP, based upon the address.
5. When the target device generates the Completion TLP, it copies the Memory Read TLP Requester ID into the corresponding Completion TLP *Requester ID* field and inserts its ID into the TLP *Completer ID* field.
6. Switches and bridges between the target device and PEX 8609 NT Port route the Completion TLP, based upon Requester ID (in this case, NT Bridge ID) information.
7. NT Port restores the original Requester ID value from the Configuration register and implements another Requester ID and Completer ID translation for the Completion TLP, before it forwards the Completion TLP to the Requester Host domain.
8. Switches and bridges between the PEX 8609 NT Port and Requester route the Completion TLP, based upon the Requester ID (in this case, NT Bridge ID).
9. Requester accepts and processes the Completion TLP.

### 15.3.2 Transaction Originating in Local Host Domain

The translation of outgoing Requests from the NT Port Virtual Interface to the NT Port Link Interface uses an 8-entry LUT, as discussed in [Section 16.14.2, “NT Port Virtual Interface NT Bridging-Specific Registers – Requester ID Translation Lookup Table Entry \(Addresses D94h – DB0h\).”](#) Each LUT entry supports all outgoing Requests and any quantity of outstanding Requests made by a single device or function. If a device uses Phantom Function Numbers to increase the maximum quantity of outstanding transactions, each phantom function consumes an LUT entry. Configure the LUT by a serial EEPROM, I<sup>2</sup>C, and/or local firmware, so it is possible to transmit Requests to the System Host domain, which provides a measure of security and protection.

When a Memory Request arrives at the NT Port Virtual Interface, the packet Requester ID is associated with this LUT. If it attains one of the enabled LUT entries, the corresponding entry address (TxIndex) is inserted into the *Function Number* field of the packet's Requester ID. Conversely, if it does not match one of the enabled LUT entries, an Unsupported Request (UR) Completion is returned.

At the same time, the contents of the NT Port Link Interface **Bus Number** and **Device Number Capture** registers (the values used during the last CSR Write to the Port) are copied into the packet Requester ID's *Bus Number* and *Device Number* fields.

A Completion, with translated Requester ID, returned from the System Host domain to the PEX 8609, is recognized when its Requester ID Bus Number and Device Number match the NT Port Link Interface captured Bus Number and Device Number. (Refer to [Figure 15-11.](#))

When the original Requester ID is restored, the following occurs:

1. TxIndex is retrieved from the *Function Number* field of the Completion TLP Requester ID.
2. TxIndex is used to look up the same 8-entry LUT, to restore the original Requester ID.
3. If the selected entry is valid, the restored Requester ID is placed into the Completion *TLP Requester* field; otherwise, an Unexpected Completion is reported.
4. Completion TLP *Completer ID* field is replaced by the NT Port Virtual Interface captured Bus Number, Device Number, and Function Number.
5. Translated Completion TLP is forwarded to the original Requester, in the Local Host domain.

**Figure 15-11. Requester ID Translation for Request Originating in Local Host Domain**

### 15.3.3 Transaction Originating in System Host Domain

Transactions originating in the System Host domain use a Receive LUT, with 32 entries, as discussed in [Section 17.15.1, “NT Port Link Interface Bridging-Specific Registers – Requester ID Translation Lookup Table Entry \(Addresses DB4h – DF0h\).”](#) This data structure supports up to 32 devices (elsewhere in the System Host domain) that are transmitting Requests through the associated NT Port. Because the Function Number is not used in the LUT association, a separate LUT entry is not required for each requesting or phantom function device. Configure the LUT before transmitting Requests through the NT Port. This Requester registration process, which cannot be accomplished by a peer, is an effective security and protection mechanism.

When a Request is received from the System Host domain and routed to the NT Port, its Requester ID is translated again – Bus Number and Device Number, but not Function Number. The received Memory Request TLP Requester ID is associated with this LUT, and the address (RxIndex) of the corresponding matching entry is substituted into the *Device Number* field of the Memory Request’s TLP *Requester ID* field.

If no match is found, or the matched entry is not enabled, the Request receives a UR response. If a match is found, and matched entry is enabled, the PEX 8609 internal virtual PCI Bus Number is copied into the packet Requester ID’s *Bus Number* field. The translated Memory Request TLP is address-translated and forwarded into the Local Host domain.

The PEX 8609 internal virtual PCI Bus Number is sufficient to route the Completion from the Completer back to the NT Port in the Completer’s domain, because the NT Port is the only possible Requester on the switch internal virtual PCI Bus. Elsewhere within the PCI Express hierarchy, the Bus Number is sufficient to route the Completion back into the switch containing the NT Port.

The inverse translation occurs when a Completion passes through the NT bridge from the Local Host domain to the System Host domain. The RxIndex is retrieved from the *Device Number* field of the received Completion TLP *Requester ID* Header field, and used to look up the 32-entry LUT. The Completion TLP *Requester ID*, *Bus Number*, and *Device Number* fields are replaced by the decoded LUT-entry Bus Number and Device Number values, if the entry is valid; otherwise, an Unexpected Completion is reported.

The Completion TLP Completer ID is replaced by the NT Port Link Interface captured Bus Number, Device Number, and Function Number values before forwarding the Completion TLP to the System Host domain. (Refer to [Figure 15-12.](#))

**Figure 15-12. Requester ID Translation for Request Originating in System Host Domain**

## 15.4 Traffic Class Translation

For Memory Requests originating from the NT Port, the Traffic Class (TC) Translation registers can be programmed to translate the original Traffic Class of the TLP to a higher-priority Traffic Class (TC[7-1]). This TC translation allows use for both VC resources available in the PEX 8609, for traffic differentiation and Quality of Service (QoS). Most Root Complexes implement a single Virtual Channel (VC). With a single VC implementation, there is no differentiation of traffic, because all Requests and Completions are queued, in order, in the same VC resources. Moreover, typically, Root Complexes support a single Traffic Class, TC0, when generating Requests.

The NT Port can be used to provide a separate path to the CPU. However, because the Root Complex can support only TC0, the TC translation allows the PEX 8609 to modify the Traffic Class for incoming TLPs, thus providing traffic differentiation.

For Posted TLPs (Memory Writes) received at the NT Port Link Interface, the PEX 8609 modifies the current TC in the packet Header, with the programmed TC. The updated TLP can make use of the multiple Virtual Channels available in the PEX 8609.

For Non-Posted TLPs (Memory Reads), the PEX 8609 changes the TC of the Memory Read Request so that it can take advantage of any additional VC resources. When the Target responds with a Completion, the PEX 8609 changes the Completion TC of the Completion back to the original TC (TC0), before the TC is forwarded out from the NT Port Link Interface. The TC Translation registers are located in the NT Port Link Interface, at register offset [960h](#).

## 15.5 NT Port Power Management Handling

### 15.5.1 Active State Power Management

The NT Port Link Interface endpoint supports the Active State Power Management (ASPM) L0s and L1 Link PM states. The NT Port Virtual Interface endpoint implements the CSRs for ASPM support. However, it does not enter into the low-power states, because there is no physical Link associated with it.

The PEX 8609 Transparent Ports also support the ASPM L0s and L1 Link PM states in Transparent mode.

### 15.5.2 PCI-PM and PME Turn Off Support

When NT mode is enabled, the NT Port Link Interface Type 0 endpoint behaves as any other endpoints in the PCI Express PCI-PM D3hot Device PM state. Once in the D3hot Device PM state, the NT Port Link Interface Type 0 endpoint Requests PCI-PM L1 Link PM state entry and finally settles in the L1 Link PM state. Only Configuration accesses and Messages to the NT Port Link Interface Type 0 endpoint are supported in the D3hot Device PM state. The Root Complex transmits PME\_Turn\_Off Messages when the NT Host decides to turn Off the main power and Reference Clock. The PEX 8609 NT Port Link Interface Type 0 endpoint indicates its readiness to lose power, by transmitting a PME\_TO\_Ack Message toward the upstream device. The PME\_TO\_Ack Message is transmitted when there are no pending TLPs to transmit upstream, toward the NT Port Link Interface. The Port Requests the L2/L3 Ready Link PM state, by transmitting PM\_Enter\_L23 Data Link Layer Packets (DLLPs) to the upstream device after transmitting a PME\_TO\_Ack TLP. The Port settles into the L3 Link PM state when the Power Controller removes the main power and Reference Clock.

When the PME\_Turn\_Off Message is received on the PEX 8609 Transparent upstream Port, the Port broadcasts this Message to all PEX 8609 downstream devices, including the NT Port Virtual Interface Type 0 endpoint. After the PME\_TO\_Ack Message is received from all downstream devices and the PEX 8609 NT Port Virtual Interface Type 0 endpoint, the PEX 8609 Transparent upstream Port transmits an aggregated PME\_TO\_Ack Message to the upstream component after it finishes transmitting all pending TLPs to the upstream component. When NT mode is enabled, the PEX 8609 Transparent downstream Ports allow the attached devices to enter the PCI-PM-compatible L1 Link PM state. The PEX 8609 NT Port Virtual Interface Type 0 endpoint never enters the PCI-PM L1 Link PM state.

### 15.5.3 Message Generation

The PEX 8609 NT Port Link Interface Type 0 endpoint never generates PM\_PME Messages. The PEX 8609 NT Port Virtual Interface Type 0 endpoint never receives Set\_Slot\_Power\_Limit Messages nor generates PM\_PME Messages.

## 15.6 Expansion ROM

The NT Port Link Interface supports Expansion ROM, by default. Expansion ROM support can be moved from the NT Port Link Interface to the NT Port Virtual Interface, by Setting the **Ingress Control** register *Expansion ROM Virtual Side* bit (NT Port Virtual Interface if Port 0 is a Legacy NT Port, offset 660h[23]).

The NT Port supports 16- or 32-KB-sized Expansion ROM, based upon the **Serial EEPROM Clock Frequency** register *Expansion ROM Size* bit (NT Port Virtual Interface if Port 0 is a Legacy NT Port, offset 268h[16]) value.

**Note:** *Expansion ROM can be enabled in either the NT Port Virtual Interface or NT Port Link Interface, but not both simultaneously. Expansion ROM is enabled, by default, in the NT Port Link Interface (**Ingress Control** register *Expansion ROM Virtual Side* bit is Cleared).*

## 15.7 NT Port Interrupts

The NT Port Virtual and Link Interfaces can both generate interrupts in response to specific events. The NT Port must not receive any INTx Message Requests. If the NT Port receives an INTx Message Request, the Request is handled as a Malformed TLP error.

### 15.7.1 NT Port Virtual Interface Interrupts

The NT Port Virtual Interface generates interrupts to the Local Host for the following reasons (all are masked, by default, and must not be masked to be enabled):

- Doorbell interrupts
- NT Port Link Interface detected an Correctable TLP error
- NT Port Link Interface detected an Uncorrectable TLP error (option to signal Fatal and/or Non-Fatal)
- NT Port Link Interface *DL\_Active* state change
- NT Port Link Interface received an Uncorrectable Error Message

NT-Virtual Doorbell interrupts and NT-Link errors and events can use the INTx, MSI, or **PEX\_INTA#** signaling mechanisms (all mutually exclusive), as follows:

- **PEX\_INTA#** output can be enabled for NT-Virtual Doorbell interrupts, by Setting the **ECC Error Check Disable** register *Enable PEX\_INTA# Interrupt Output(s) for NT-Virtual Doorbell-Generated Interrupts* bit (NT Port Virtual Interface, or Port 0 if Port 0 is the NT Port, offset 1C8h[7]).
- **PEX\_INTA#** output can be enabled for NT-Link Error and Event interrupts, by Setting the register's *Enable PEX\_INTA# Interrupt Output(s) for Device-Specific Error-Triggered Interrupts* bit (offset 1C8h[5])

Refer to [Section 15.1.6](#) for Doorbell interrupt details.

The NT Port Virtual Interface de-asserts INTx or **PEX\_INTA#** interrupts in response to one or more of the following conditions:

- NT Port Virtual Interface **PCI Command** register *Interrupt Disable* bit (offset 04h[10]) is Set
- Corresponding *Interrupt Mask* bit is Set
- NT Port Link goes down (*DL\_Down* condition) or the NT Port Link Interface receives a Hot Reset
- Software Clears the *Interrupt Status* bit, or Sets the *Doorbell Interrupt Request Clear* bit

In NT PCI-to-PCI Bridge mode, for tracking purposes, an NT Port Virtual Interface-generated interrupt is treated like an event that is external to the PCI-to-PCI bridge. If software asserts a [Secondary Bus Reset](#) from this PCI-to-PCI bridge, the PCI-to-PCI bridge de-asserts the NT Port Virtual Interface interrupt.

When the NT Port Link Interface detects Correctable TLP errors, the NT Port Virtual Interface signals the interrupt to the Local Host, if the interrupt signaling is enabled and not masked (**Link Error Status Virtual** register [Link Side Correctable Error Status](#) bit is Set, and **Link Error Mask Virtual** register [Link Side Correctable Error Mask](#) bit is Cleared (NT Port Virtual Interface as Port 0, offsets FE0h[0] and FE4h[0]), respectively).

When the NT Port Link Interface detects Uncorrectable TLP errors, the NT Port Virtual Interface signals the interrupt to the Local Host, if the interrupt signaling is enabled and not masked (**Link Error Status Virtual** register [Link Side Uncorrectable Error Status](#) bit is Set, and **Link Error Mask Virtual** register [Link Side Uncorrectable Error Mask](#) bit is Cleared (NT Port Virtual Interface as Port 0, offsets FE0h[1] and FE4h[1]), respectively).

An NT Port Link Interface *DL\_Active* state change occurs upon detection of an NT Port Link Interface *DL\_Down* state rise edge and fall edge. This signals the interrupt to the Local Host, if the interrupt signaling is enabled and not masked (**Link Error Status Virtual** register [Link Side DL Active Change Status](#) bit is Set, and **Link Error Mask Virtual** register [Link Side DL Active Change Mask](#) bit is Cleared (NT Port Virtual Interface as Port 0, offsets FE0h[2] and FE4h[2]), respectively).

When the NT Port Link Interface receives an Uncorrectable Error Message, the NT Port Virtual Interface signals the interrupt to the Local Host, if the interrupt signaling is enabled and not masked (**Link Error Status Virtual** register [Link Side Uncorrectable Error Message Drop Status](#) bit is Set, and **Link Error Mask Virtual** register [Link Side Uncorrectable Error Message Drop Mask](#) bit is Cleared (NT Port Virtual Interface as Port 0, offsets FE0h[3] and FE4h[3]), respectively).

## 15.7.2 NT Port Link Interface Interrupts

The NT Port Link Interface generates interrupts to the System Host for NT-Link Doorbell interrupts detected at the NT Port Link Interface ingress Port (interrupts are masked, by default). The NT Port Link Interface should not detect any Device-Specific errors.

NT-Link Doorbell interrupts can use the INTx, MSI, or [PEX\\_INTA#](#) signaling mechanisms (all mutually exclusive). [PEX\\_INTA#](#) output can be enabled for NT-Link Doorbell interrupts, by Setting the **ECC Error Check Disable** register [Enable PEX\\_INTA# Interrupt Output\(s\) for NT-Link Doorbell-Generated Interrupts](#) bit (NT Port Link Interface, offset 1C8h[7]). Refer to [Section 15.1.6](#) for Doorbell interrupt details.

The NT Port Link Interface de-asserts INTx or [PEX\\_INTA#](#) interrupts in response to one or more of the following conditions:

- NT Port Link Interface **PCI Command** register [Interrupt Disable](#) bit (offset 04h[10]) is Set
- Corresponding [Interrupt Mask](#) bit is Set
- NT Port Link goes down (*DL\_Down* condition) or the NT Port Link Interface receives a Hot Reset
- Software Clears the [Interrupt Status](#) bit, or Sets the [Doorbell Interrupt Request Clear](#) bit

## 15.8 NT Port Error Handling

The PEX 8609 NT Port Virtual Interface endpoint logs TLP errors, for TLPs that travel from the NT Port Virtual Interface to the NT Port Link Interface. The PEX 8609 signals Error Messages to the Local Host (Host closest to the upstream Port). The PEX 8609 provides an option to communicate this error condition to the System Host (Host closest to the NT Port), by signaling an interrupt.

The PEX 8609 NT Port Link Interface endpoint logs TLP errors, for TLPs that travel from the NT Port Link Interface to the NT Port Virtual Interface. The PEX 8609 signals Error Messages to the System Host (Host closest to the NT Port).

When the PEX 8609 receives a TLP, it performs the following:

1. TLP integrity check,
2. Address decode,
3. Address translation,
4. Requester ID translation, and
5. ECRC re-generation,

before transmitting the TLP through the NT Port. If the PEX 8609 detects an ECRC error, it corrupts the re-generated ECRC before transmitting the TLP through the NT Port. The PEX 8609 also provides options for dropping error-detected ECRC or endpoint (EP) TLPs (**Ingress Control Shadow** register *Drop ECRC TLPs* and *Drop EP TLPs* bits (NT Port Virtual Interface if Port 0 is a Legacy NT Port, offset 664h[8, 4], respectively)).

The PEX 8609 does not generate the ECRC for a TLP that passes through the NT Port, if the received TLP does not have its *TD* bit Set.

The PEX 8609 drops all TLPs traveling from the NT Port Virtual Interface to the NT Port Link Interface, if the internal RAM Fatal ECC error is detected, until the PEX 8609 receives a Hot Reset from a Local Host.

## 15.8.1 NT Port Link Interface Error Handling

If the NT Port Link Interface receives an Uncorrectable Error message, it reports a Malformed TLP error, by default. However, if the **Ingress Control Shadow** register *NT Error Message Drop* bit (NT Port Virtual Interface if Port 0 is a Legacy NT Port, offset 664h[11]) is Set, the NT Port Link Interface drops the Message, and logs the error in the **Link Error Status Virtual** register *Link Side Uncorrectable Error Message Drop Status* bit (NT Port Virtual Interface as Port 0, offset FE0h[3]). If the corresponding **Link Error Mask Virtual** register *Link Side Uncorrectable Error Message Drop Mask* bit (NT Port Virtual Interface as Port 0, offset FE4h[3]) is Set, the NT Port Virtual signals an interrupt (INTx, MSI, or PEX\_INTA#) to the Local Host through the upstream Port, if interrupts are enabled.

## 15.8.2 NT PCI-to-PCI Bridge Mode Error Handling

In NT PCI-to-PCI Bridge mode, for the NT Port Virtual Interface to generate an Error Message, the following error-forwarding *Enable* bits, in both the NT PCI-to-PCI bridge and the upstream Port, must be Set:

- **PCI Command** register (offset 04h)
  - *SERR# Enable* (bit 8)
- **Bridge Control** register (offset 3Ch)
  - *SERR# Enable* (bit 17)
- **Device Control** register (offset 70h)
  - *Correctable Error Reporting Enable* (bit 0)
  - *Non-Fatal Error Reporting Enable* (bit 1)
  - *Fatal Error Reporting Enable* (bit 2)

When the NT Port Virtual Interface generates an error Message, the NT PCI-to-PCI bridge also logs the error status in the following NT PCI-to-PCI Bridge mode registers, while sending the Message in the upstream direction:

- **Secondary Status** register (offset 1Ch)
  - *Received System Error* (bit 30)
- **PCI Status** register (offset 04h)
  - *Signaled System Error* (bit 30)

## 15.9 Cursor Mechanism

A software application can use the [Device-Specific Cursor Mechanism](#) to access the PEX 8609 NT Port Configuration Space registers. The registers that support the Device-Specific Cursor Mechanism are the [Configuration Address Window](#) and [Configuration Data Window](#) registers (offsets F8h and FCh, respectively). A software application can also:

- Select the Configuration Register offset, by using the **Configuration Address Window** register
- Perform Read accesses to the **Configuration Data Window** register, to read to the selected Configuration register
- Perform Write accesses to the **Configuration Data Window** register, to write to the selected Configuration register

Configuration transactions have access to this Device-Specific Cursor Mechanism, if NT mode is enabled.

For details regarding the **Configuration Address Window** and **Configuration Data Window** registers, refer to:

- [Section 16.10, “NT Port Virtual Interface Vendor-Specific Capability 3 Registers \(Offsets C8h – FCh\)”](#)
- [Section 17.10, “NT Port Link Interface Vendor-Specific Capability 3 Registers \(Offsets C8h – FCh\)”](#)

## 15.10 Port Programmability

The PEX 8609 supports the capability of programming the upstream Port and NT Port Number. The Configuration register for the upstream Port and NT Port is in the **Debug Control** register [Upstream Port ID](#) and [NT Port Number](#) fields (NT Port Virtual Interface if Port 0 is a Legacy NT Port, offset 1DCh[11:8, 27:24], respectively). This register is updated, based upon the external [STRAP\\_NT\\_ENABLE#](#) and [STRAP\\_NT\\_UPSTRM\\_PORTSEL\[3:0\]](#) inputs, by default. A serial EEPROM, I<sup>2</sup>C, and/or software can be used to override the external strap values.

A software application can change the upstream Port and NT Port location to another Port Number during runtime, or as part of a failover sequence. It is recommended that the PEX 8609 be in an Idle state (no traffic) when changing the upstream Port and NT Port Numbers during runtime. During a failover sequence, application software must be able to handle all spurious TLPs that it receives as a result of the failover process.

## Chapter 16 NT Port Virtual Interface Registers – NT Mode Only

### 16.1 Introduction

**Note:** Check the latest design guides, application notes and errata list for Non-Transparent (NT) usage.

The NT Port includes two sets of Configuration, Capability, Control, and Status registers, to support the Virtual and Link Interfaces. This chapter defines the NT Port Virtual Interface registers. Other registers are defined in:

- [Chapter 14, “Transparent Port Registers”](#)
- [Chapter 17, “NT Port Link Interface Registers – NT Mode Only”](#)
- [Chapter 18, “DMA Interface Registers – DMA Mode Only”](#)

**Note:** For Chip-specific registers (those that exist only in Port 0), if Port 0 is a Legacy NT Port, then those registers exist only in the NT Port Virtual Interface.

All PEX 8609 registers can be accessed by Configuration or Memory Requests.

For further details regarding register names and descriptions, refer to the following specifications:

- *PCI r3.0*
- *PCI Power Mgmt. r1.2*
- *PCI Express Base r2.0*

## 16.2 NT Port Virtual Interface Type 0 Register Map

Table 16-1 defines the NT Port Virtual Interface Type 0 register mapping.

## 16.3 Register Access

The PEX 8609 NT Port Virtual Interface implements a 4-KB Configuration Space. The lower 256 bytes (offsets 00h through FFh) comprise the PCI-compatible Configuration Space, and the upper 960 Dwords (offsets 100h through FFFh) comprise the PCI Express Extended Configuration Space. The PEX 8609 supports three mechanisms for accessing the NT Port Virtual Interface registers:

- [PCI Express Base r2.0 Configuration Mechanism](#)
- [Device-Specific Memory-Mapped Configuration Mechanism](#)
- [Device-Specific Cursor Mechanism](#)

### 16.3.1 *PCI Express Base r2.0* Configuration Mechanism

The *PCI Express Base r2.0* Configuration mechanism is divided into two mechanisms:

- [PCI r3.0-Compatible Configuration Mechanism](#) – Provides Conventional PCI access to the first 256 bytes (the bytes at offsets 00h through FFh) of the NT Port Virtual Interface Configuration Register space
- [PCI Express Enhanced Configuration Access Mechanism](#) – Provides access to the entire 4-KB Configuration Space

Both are described in the sections that follow.

#### 16.3.1.1 *PCI r3.0-Compatible* Configuration Mechanism

The *PCI r3.0-Compatible* Configuration mechanism provides standard access to the PEX 8609 NT Port Virtual Interface's first 256 bytes (the bytes at offsets 00h through FFh) of the PCI Express Configuration Space. (Refer to [Figure 16-1](#).)

The mechanism uses PCI Type 0 and Type 1 Configuration transactions to access the PEX 8609 Configuration registers. All Ports capture the Bus Number and Device Number assigned by the upstream device on the PCI Express Link attached to the PEX 8609 upstream Port, as required by the *PCI Express Base r2.0*.

The PEX 8609 decodes all Type 1 Configuration accesses received on its upstream Port, when any of the following conditions exist:

- If the Bus Number specified in the Configuration access is the Bus Number of the PEX 8609 internal virtual PCI Bus, the PEX 8609 automatically converts the Type 1 Configuration access into the appropriate Type 0 Configuration access for the specified device.
  - If the specified device corresponds to the NT Port Virtual Interface (or to the PCI-to-PCI bridge in one of the PEX 8609 Transparent downstream Ports), the PEX 8609 processes the Read or Write Request
  - If the specified Device Number does not correspond to any of the PEX 8609 downstream Port Device Numbers nor NT Port Number, the PEX 8609 responds with an Unsupported Request (UR)

This mechanism uses the same Request format as the [PCI Express Enhanced Configuration Access Mechanism](#). For PCI-compatible Configuration Requests, the *Extended Register Address* field must be all zeros (0).

Because the mechanism is limited to the first 256 bytes of the NT Port Virtual Interface Configuration register space, one of the following must be used to access beyond Byte FFh:

- [PCI Express Enhanced Configuration Access Mechanism](#)
- [Device-Specific Memory-Mapped Configuration Mechanism](#)
- [Device-Specific Cursor Mechanism](#)

#### **16.3.1.2 PCI Express Enhanced Configuration Access Mechanism**

The PCI Express Enhanced Configuration Access mechanism uses a flat, Root Complex Memory-Mapped Address space to access the device Configuration registers. In this case, the Memory address determines the Configuration register accessed, and the Memory data returns the addressed register's contents. The Root Complex converts the Memory transaction into a Configuration transaction.

This mechanism can be used to access all PEX 8609 Configuration registers.

### 16.3.2 Device-Specific Memory-Mapped Configuration Mechanism

The Device-Specific Memory-Mapped Configuration mechanism provides a method to access the registers for all Ports within a single 128-KB Memory map, as illustrated in [Figure 16-1](#). This Memory map is identical for Upstream Port **BAR0/1**, NT Port Virtual Interface **BAR0/1**, and NT Port Link Interface **BAR0/1**. The registers of each Port are located within a 4-KB range.

When the NT Port is enabled at Fundamental Reset, the NT Port Virtual and Link Interface registers use the *PCI r3.0* Type 0 Configuration Space Header. In NT PCI-to-PCI Bridge mode (*STRAP\_NT\_P2P\_EN#*=L), the NT PCI-to-PCI bridge (between the NT Port Virtual Interface and internal virtual PCI Bus) registers use the *PCI r3.0* Type 1 Configuration Space Header, and are mapped to the 4-KB Address space of the Port Number that is assigned as the NT Port (indicated in the [Debug Control](#) register *NT Port Number* field (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offset 1DCh[27:24])).

To use this mechanism, use the [PCI r3.0-Compatible Configuration Mechanism](#) to program the PEX 8609 NT Port Virtual Interface [Base Address 0](#) and [Base Address 1](#) registers (**BAR0** and **BAR1**, offsets 10h and 14h, respectively). After the PEX 8609 NT Port Virtual Interface Memory-Mapped register Base address is Set, the PEX 8609 Configuration Space registers are accessed, using Memory Reads and Writes to the 4-KB range, starting at offset 64 KB (1\_0000h, Virtual Interface) and offset 68 KB (1\_1000h, Link Interface).

**Figure 16-1. NT Mode Configuration Register Mapping to Memory-Mapped BAR****PEX 8609**

|                           |                 |
|---------------------------|-----------------|

### 16.3.3 Device-Specific Cursor Mechanism

The Device-Specific Cursor mechanism is provided for use in development systems that can only generate *PCI r3.0* Configuration cycles (*that is*, the system cannot use either the [Device-Specific Memory-Mapped Configuration Mechanism](#), nor generate Extended Configuration Requests to access the Extended Configuration Space).

In [Figure 16-2](#), the software uses the **Configuration Address Window** (CFGADDR) register (offset **F8h**) to point to the NT Port Virtual or Link Interface Configuration Space registers, including the PCI Express Extended Configuration Space registers (offsets 100h through FFFh).

Software uses the **Configuration Data Window** (CFGDATA) register (offset **FCh**) to write to or read from the selected Configuration Space registers.

Refer to [Section 16.10](#), “NT Port Virtual Interface Vendor-Specific Capability 3 Registers (Offsets C8h – FCh),” for the register descriptions.

**Figure 16-2. Configuration Space View**

## 16.4 Register Descriptions

The remainder of this chapter details the PEX 8609 NT Port Virtual Interface registers, including:

- Bit/field names
- Description of register functions in the PEX 8609 NT Port Virtual and Link Interfaces
- Type (*such as* RW or HwInit; refer to [Table 14-5](#), “Register Types, Grouped by User Accessibility,” for Type descriptions)
- Whether the power-on/reset value can be modified, by way of the PEX 8609 serial EEPROM and/or I<sup>2</sup>C/SMBus Initialization feature
- Default power-on/reset value

## 16.5 NT Port Virtual Interface PCI-Compatible Type 0 Configuration Header Registers (Offsets 00h – 3Ch)

This section details the NT Port Virtual Interface PCI-Compatible Type 0 Configuration Header registers. [Table 16-2](#) defines the register map.

**Table 16-2. NT Port Virtual Interface PCI-Compatible Type 0 Configuration Header Register Map**

### Register 16-1. 00h PCI Configuration ID

| Bit(s) | Description                                                                                                                                                                   | Type | Serial EEPROM and I <sup>2</sup> C | Default |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|------------------------------------|---------|
| 15:0   | <b>Vendor ID</b><br>Identifies the device manufacturer. Defaults to the PCI-SIG-issued Vendor ID of PLX (10B5h), if not overwritten by serial EEPROM and/or I <sup>2</sup> C. | RO   | Yes                                | 10B5h   |
| 31:16  | <b>Device ID</b><br>Identifies the particular device. Defaults to the PLX part number for the PEX 8609, if not overwritten by serial EEPROM and/or I <sup>2</sup> C.          | RO   | Yes                                | 8609h   |

**Register 16-2. 04h PCI Command/Status**

| Bit(s)             | Description                                                                                                                                                                                                                                                                                                                                                                                                    | Type  | Serial EEPROM and I <sup>2</sup> C | Default |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|------------------------------------|---------|
| <b>PCI Command</b> |                                                                                                                                                                                                                                                                                                                                                                                                                |       |                                    |         |
| 0                  | <b>I/O Access Enable</b><br>The PEX 8609 does not claim I/O resources, nor does it forward I/O transactions through the NT Port. The value of this register is “Don’t Care.”                                                                                                                                                                                                                                   | RW    | Yes                                | 0       |
| 1                  | <b>Memory Access Enable</b><br>0 = PEX 8609 ignores Memory Space Requests on the NT Port Virtual Interface<br>1 = PEX 8609 accepts Memory Space Requests received on the NT Port Virtual Interface                                                                                                                                                                                                             | RW    | Yes                                | 0       |
| 2                  | <b>Bus Master Enable</b><br>Controls PEX 8609 forwarding of Memory Requests upstream. Does not affect Message forwarding nor Completions.<br>0 = PEX 8609 handles Memory Requests received on the NT Port Link Interface as Unsupported Requests (UR); for Non-Posted Requests, the PEX 8609 returns a Completion with UR Completion status<br>1 = PEX 8609 forwards Memory Requests in the upstream direction | RW    | Yes                                | 0       |
| 3                  | <b>Special Cycle Enable</b><br><i>Not supported</i><br>Cleared, as required by the <i>PCI Express Base r2.0</i> .                                                                                                                                                                                                                                                                                              | RsvdP | No                                 | 0       |

- a. With no serial EEPROM nor previous I<sup>2</sup>C programming, Reads return 00h for the **Data** and **Data Scale** registers (for all *Data Selects*).

# 16.7 NT Port Virtual Interface MSI Capability Registers (Offsets 48h – 64h)

The registers detailed in [Section 14.8, “MSI Capability Registers \(Offsets 48h – 64h\),”](#) are also applicable to the NT Port Virtual Interface. [Table 16-4](#) defines the register map used by the NT Port Virtual Interface.

**Table 16-4. NT Port Virtual Interface MSI Capability Register Map<sup>a</sup>**

|                         |                         |                       |                 |                               |

## 16.10 NT Port Virtual Interface Vendor-Specific Capability 3 Registers (Offsets C8h – FCh)

This section details the NT Port Virtual Interface Vendor-Specific Capability 3 registers, which include the **Memory BARx Setup** registers and **Configuration Address** and **Data Window** registers. Table 16-7 defines the register map used by the NT Port.

The **NT Port Virtual Interface BARx Setup** (offsets D0h through E0h) register values are shadowed in the corresponding **NT Port Virtual Interface BARx Setup Shadow** registers (offsets D80h through D90h, respectively). When software writes to an **NT Port Virtual Interface BARx Setup** register, the value is automatically copied to the corresponding **NT Port Virtual Interface BARx Setup (Shadow Copy)** register. If the **NT Port Virtual Interface BARx Setup** registers are programmed by serial EEPROM, the **NT Port Virtual Interface BARx Setup (Shadow Copy)** registers must also be programmed by serial EEPROM, to the same respective register values.

The Cursor Mechanism registers at offsets F8h and FCh provide a means for accessing PCI Express Extended Configuration Space registers (offsets 100h through FFFh) within the NT Port Virtual and Link Interfaces, when only standard PCI Configuration transactions (that do not support the *Extended Register Number* field within the Completion Request Header) are available. The Cursor Mechanism can generally access only those registers that are defined by the *PCI Express Base r2.0*, and not the Device-Specific registers. However, if Port 0 is a Legacy NT Port, the Cursor Mechanism in the NT Port Virtual Interface registers can also access the Device-Specific registers.

**Table 16-7. NT Port Virtual Interface Vendor-Specific Capability 3 Register Map**

## 16.12.1 NT Port Virtual Interface WRR Port Arbitration Table Registers (Offsets 1A8h – 1BCh)

The registers detailed in [Section 14.13.1, “WRR Port Arbitration Table Registers \(Offsets 1A8h – 1BCh\),”](#) are also applicable to the NT Port Virtual Interface if the NT Port is the upstream Port (refer to the Note). Port Arbitration Table phases are used to determine Port weighting during “Weighted Round-Robin with 32 Phases” Port arbitration.

[Table 16-10](#) defines the register map used by the NT Port Virtual Interface. The numbers along the top of the table indicate the 4-bit fields of each 32-bit register. There are 32 phases, and any active Port Number can go into each Port x Phase x box.

**Notes:** *The Port Arbitration Table is used only when Weighted Round-Robin (WRR) with 32-phase Port Arbitration is selected. The Arbiter is parked on the upstream Port, if the upstream Port is Port 0 through Port 3. Moreover, the fields within this register are valid only on the upstream Port. If the upstream Port is on a higher-numbered Port, the Arbiter is parked on Port 0. Furthermore, the fields within this register are valid only on Port 0 and reserved on all other Ports.*

*This register structure is reserved in NT PCI-to-PCI Bridge mode.*

**Table 16-10. NT Port Virtual Interface WRR Port Arbitration Table Register Map (When WRR is enabled)**

| Reserved        |                 |                 |                 |                 |                 |                 |                 | 1B8h – 1BCh |

## 16.13 NT Port Virtual Interface Device-Specific Registers (Offsets 1C0h – C88h)

The registers detailed in [Section 14.14, “Device-Specific Registers \(Offsets 1C0h – 51Ch\),”](#) and [Section 14.16, “Device-Specific Registers \(Offsets 530h – F8Ch\)”](#) (for offsets 558h through C88h), are unique to the PEX 8609 and not referenced in the *PCI Express Base r2.0*. These registers are also applicable to the NT Port Virtual Interface, except as defined in [Table 16-11](#) (register map) through [Table 16-15](#), and [Register 16-36](#) through [Register 16-65](#).

Other NT Port Virtual Interface Device-Specific registers are detailed in:

- [Section 16.15, “NT Port Virtual Interface Device-Specific Registers \(Offsets E40h – F8Ch\)”](#)
- [Section 16.17, “NT Port Virtual Interface Device-Specific Registers – Link Error \(Offsets FE0h – FFCh\)”](#)

**Note:** *It is recommended that these registers not be changed from their default values.*

### 16.13.1 NT Port Virtual Interface Device-Specific Registers – Error Checking and Debug (Offsets 1C0h – 1FCh)

The registers detailed in [Section 14.14.1, “Device-Specific Registers – Error Checking and Debug \(Offsets 1C0h – 1FCh\)”](#) are also applicable to the NT Port Virtual Interface, except as defined in [Table 16-12](#) (register map; offset 1E4h is **reserved**), and [Register 16-36](#) through [Register 16-40](#).

**Table 16-12. NT Port Virtual Interface Device-Specific Error Checking and Debug Register Map (Ports<sup>a</sup>)**

| 31 30 29 28 27 26 25 24                                                                                      | 23 22 21 20 19 18 17 16 | 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0 |      |
|--------------------------------------------------------------------------------------------------------------|-------------------------|---------------------------------------|------|

After the register is written, either by software and/or serial EEPROM, this bit is Set, and Cleared only by a Fundamental Reset.                                             | RO    | No                                 | 0       |

### 16.13.2 NT Port Virtual Interface Device-Specific Registers – Ingress Control and Port Enable (Offsets 660h – 67Ch)

The registers detailed in [Section 14.16.5, “Device-Specific Registers – Ingress Control and Port Enable \(Offsets 660h – 67Ch\),”](#) are also applicable to the NT Port Virtual Interface, except as defined in [Table 16-13](#) (register map), and [Register 16-41](#) and [Register 16-42](#).

**Table 16-13. NT Port Virtual Interface Device-Specific Ingress Control and Port Enable Register Map**

## 16.13.4 NT Port Virtual Interface Device-Specific Registers – Vendor-Specific Extended Capability 4 (Offsets C34h – C88h)

This section details the NT Port Virtual Interface Device-Specific, Vendor-Specific Extended Capability 4 registers, which include the **Memory BARx Address Translation**, **Doorbell**, and **Scratchpad** registers. Table 16-15 defines the register map used by the NT Port Virtual Interface.

**Table 16-15. NT Port Virtual Interface Device-Specific, Vendor-Specific Extended Capability 4 Register Map**

### 16.14.1 NT Port Virtual Interface NT Bridging-Specific Registers – Base Address and Base Address Setup (Offsets D68h – D90h)

The registers in this section are shadow copies of the NT Port Virtual Interface Base Address register (BAR) and BAR Configuration registers, and valid only for Port 0. If Port 0 is the NT Port, the registers are in Virtual Interface Configuration Space. [Table 16-17](#) defines the register map.

**Notes:** *This register structure is reserved in NT PCI-to-PCI Bridge mode.*

*It is recommended that these registers not be changed from their default values.*

**Table 16-17. NT Port Virtual Interface NT Bridging-Specific Base Address  
Register (BAR) and BARx Setup Register Map  
(Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port)**

## 16.14.2 NT Port Virtual Interface NT Bridging-Specific Registers – Requester ID Translation Lookup Table Entry (Addresses D94h – DB0h)

This section describes the NT Port Virtual Interface NT Bridging-Specific Requester ID Translation Lookup Table (LUT) Entry registers. The NT Port uses these registers for Requester ID translation when it forwards:

- Memory Requests from the NT Port Virtual Interface to the NT Port Link Interface, –or–
- Completion TLPs from the NT Port Link Interface to the NT Port Virtual Interface

If the application needs to send traffic through the NT Port Virtual Interface, program the registers listed in this group with the corresponding Requester's Requester ID, then Set the *LUT Entry\_n Enable* bit (bit 31) of each register accordingly.

Table 16-18 defines the register and address locations, as they relate to Register 16-77.

**Table 16-18. NT Port Virtual Interface NT Bridging-Specific Requester ID Translation Lookup Table Entry\_n Register Locations**

| ADDR Location | Lookup Table Entry_n | ADDR Location | Lookup Table Entry_n |

## 16.15 NT Port Virtual Interface Device-Specific Registers (Offsets E40h – F8Ch)

The registers detailed in [Section 14.16, “Device-Specific Registers \(Offsets 530h – F8Ch\)”](#) (for offsets E40h through F8Ch), are unique to the PEX 8609 and not referenced in the *PCI Express Base r2.0*. These registers are also applicable to the NT Port Virtual Interface, except as defined in [Table 16-19](#) (register map) and [Table 16-22](#), and [Register 16-78](#) through [Register 16-85](#).

Other NT Port Virtual Interface Device-Specific registers are detailed in:

- [Section 16.13, “NT Port Virtual Interface Device-Specific Registers \(Offsets 1C0h – C88h\)”](#)
- [Section 16.17, “NT Port Virtual Interface Device-Specific Registers – Link Error \(Offsets FE0h – FFCh\)”](#)

**Note:** *It is recommended that these registers not be changed from their default values.*

### 16.15.3 NT Port Virtual Interface Device-Specific Registers – ARI Capability (Offsets F50h – F8Ch)

The Alternative Routing-ID Interpretation (ARI) Capability registers detailed in [Section 14.16.19, “Device-Specific Registers – ARI Capability \(Offsets F50h – F8Ch\),”](#) are also applicable to the NT Port Virtual Interface, except as defined in [Table 16-22](#) (register map), and [Register 16-78](#) through [Register 16-85](#).

**Table 16-22. NT Port Virtual Interface Device-Specific ARI Capability Register Map

## 16.16 NT Port Virtual Interface Advanced Error Reporting Extended Capability Registers (Offsets FB4h – FDCh)

The registers detailed in [Section 14.17, “Advanced Error Reporting Extended Capability Registers \(Offsets FB4h – FDCh\),”](#) are also applicable to the NT Port Virtual Interface, except for the [Next Capability Offset](#) value, as defined in [Table 16-23](#) (register map), [Register 16-86](#), and the exceptions indicated in the note.

**Notes:** Data Link Protocol and Surprise Down PCI Express errors are not valid for the NT Port Virtual nor Link Interfaces, and therefore do not affect register offsets FB8h, FBCh, and FC0h in NT mode.

*Receiver, Bad TLP, Bad DLLP, Replay Number Rollover, and Replay Timer Timeout*  
PCI Express errors are not valid for the NT Port Virtual nor Link Interfaces, and therefore do not affect register offsets FC4h and FC8h in NT mode.

**Table 16-23. NT Port Virtual Interface Advanced Error Reporting Extended Capability Register Map**

16.17 NT Port Virtual Interface Device-Specific Registers – Link Error (Offsets FE0h – FFCh)

This section details the NT Port Virtual Interface Device-Specific Link Error registers, located at offsets FE0h through FFCh. These Device-Specific registers are unique to the NT Port Virtual Interface, and not referenced in the *PCI Express Base r2.0*. Table 16-24 defines the register map used by the NT Port Virtual Interface.

Other NT Port Virtual Interface Device-Specific registers are detailed in:

- Section 16.13, “NT Port Virtual Interface Device-Specific Registers (Offsets 1C0h – C88h)”
- Section 16.15, “NT Port Virtual Interface Device-Specific Registers (Offsets E40h – F8Ch)”

*Note: It is recommended that these registers not be changed from their default values.*

Table 16-24. NT Port Virtual Interface Device-Specific Register Map – Link Error (Offsets FE0h – FFCh) (Port 0, when Port 0 is the NT Port)

## Chapter 17 NT Port Link Interface Registers – NT Mode Only

### 17.1 Introduction

**Note:** Check the latest design guides, application notes and errata list for Non-Transparent (NT) usage.

The NT Port includes two sets of Configuration, Capability, Control, and Status registers, to support the Link and Virtual Interfaces. This chapter defines the NT Port Link Interface registers. Other registers are defined in:

- [Chapter 14, “Transparent Port Registers”](#)
- [Chapter 16, “NT Port Virtual Interface Registers – NT Mode Only”](#)
- [Chapter 18, “DMA Interface Registers – DMA Mode Only”](#)

**Note:** For Chip-specific registers (those that exist only in Port 0), if Port 0 is a Legacy NT Port, then those registers exist only in the NT Port Virtual Interface.

All PEX 8609 registers can be accessed by Configuration or Memory Requests.

For further details regarding register names and descriptions, refer to the following specifications:

- *PCI r3.0*
- *PCI Power Mgmt. r1.2*
- *PCI Express Base r2.0*

## 17.2 NT Port Link Interface Type 0 Register Map

Table 17-1 defines the NT Port Link Interface Type 0 register mapping.

**Table 17-1. NT Port Link Interface Type 0 Register Map**

## 17.3 Register Access

The PEX 8609 NT Port Link Interface implements a 4-KB Configuration Space. The lower 256 bytes (offsets 00h through FFh) comprise the PCI-compatible Configuration Space, and the upper 960 Dwords (offsets 100h through FFFh) comprise the PCI Express Extended Configuration Space. The PEX 8609 supports three mechanisms for accessing the NT Port Link Interface registers:

- [PCI Express Base r2.0 Configuration Mechanism](#)
- [Device-Specific Memory-Mapped Configuration Mechanism](#)
- [Device-Specific Cursor Mechanism](#)

### 17.3.1 *PCI Express Base r2.0* Configuration Mechanism

The *PCI Express Base r2.0* mechanism is divided into two mechanisms:

- [PCI r3.0-Compatible Configuration Mechanism](#) – Provides Conventional PCI access to the first 256 bytes (the bytes at offsets 00h through FFh) of the NT Port Link Interface Configuration Register space
- [PCI Express Enhanced Configuration Access Mechanism](#) – Provides access to the entire 4-KB Configuration Space

Both are described in the sections that follow.

The PEX 8609 decodes Type 0 Configuration transactions received on its NT Port Link Interface. The PEX 8609 reads from or writes to the NT Port Link Interface register, as specified in the original Type 0 Configuration access.

#### 17.3.1.1 *PCI r3.0-Compatible* Configuration Mechanism

The *PCI r3.0-Compatible* Configuration Space consists of the first 256 bytes of the NT Port Link Interface Configuration Space. (Refer to [Figure 17-1](#).) The *PCI r3.0-Compatible* Configuration mechanism provides standard access to the PEX 8609 NT Port Link Interface's first 256 bytes (the bytes at offsets 00h through FFh) of the PCI Express Configuration Space.

This mechanism uses the same Request format as the [PCI Express Enhanced Configuration Access Mechanism](#). For PCI-compatible Configuration Requests, the *Extended Register Address* field must be all zeros (0).

Because the mechanism is limited to the first 256 bytes of the NT Port Link Interface Configuration Register space, one of the following must be used to access beyond Byte FFh:

- [PCI Express Enhanced Configuration Access Mechanism](#)
- [Device-Specific Memory-Mapped Configuration Mechanism](#)
- [Device-Specific Cursor Mechanism](#)

### 17.3.1.2 PCI Express Enhanced Configuration Access Mechanism

The PCI Express Enhanced Configuration Access mechanism uses a flat, Root Complex Memory-Mapped Address space to access the device Configuration registers. In this case, the Memory address determines the Configuration register accessed, and Memory data returns the addressed register contents. The Root Complex converts the Memory transaction into a Configuration transaction before transmitting this access to the downstream devices.

This mechanism is used to access the NT Port Link Interface Type 0 registers:

- NT Port Link Interface PCI-Compatible Type 0 Configuration Header Registers (Offsets 00h – 3Ch)
- NT Port Link Interface PCI Power Management Capability Registers (Offsets 40h – 44h)
- NT Port Link Interface MSI Capability Registers (Offsets 48h – 64h)
- NT Port Link Interface PCI Express Capability Registers (Offsets 68h – A0h)
- NT Port Link Interface Vendor-Specific Capability 3 Registers (Offsets C8h – FCh)
- NT Port Link Interface Device Serial Number Extended Capability Registers (Offsets 100h – 134h)
- NT Port Link Interface Power Budget Extended Capability Registers (Offsets 138h – 144h)
- NT Port Link Interface Virtual Channel Extended Capability Registers (Offsets 148h – 1BCh)
- NT Port Link Interface Device-Specific Registers – Vendor-Specific Extended Capability 2 (Offsets 950h – 95Ch)
- NT Port Link Interface Device-Specific Registers – Vendor-Specific Extended Capability 4 (Offsets C34h – C88h)
- NT Port Link Interface Advanced Error Reporting Extended Capability Registers (Offsets FB4h – FDCh)

## 17.3.2 Device-Specific Memory-Mapped Configuration Mechanism

The Device-Specific Memory-Mapped Configuration mechanism provides a method to access the registers for all Ports within a single 128-KB Memory map, as illustrated in [Figure 17-1](#). This Memory map is identical for Upstream Port **BAR0/1**, NT Port Virtual Interface **BAR0/1**, and NT Port Link Interface **BAR0/1**. The registers of each Port are located within a 4-KB range.

When the NT Port is enabled at Fundamental Reset, the NT Port Virtual and Link Interface registers use the *PCI r3.0* Type 0 Configuration Space Header. In NT PCI-to-PCI Bridge mode (*STRAP\_NT\_P2P\_EN#*=L), the NT PCI-to-PCI bridge (between the NT Port Virtual Interface and internal virtual PCI Bus) registers use the *PCI r3.0* Type 1 Configuration Space Header, and are mapped to the 4-KB Address space of the Port Number that is assigned as the NT Port (indicated in the **Debug Control** register *NT Port Number* field (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offset 1DCh[27:24])).

To use this mechanism, use the [PCI r3.0-Compatible Configuration Mechanism](#) to program the PEX 8609 upstream Port **Base Address 0** and **Base Address 1** registers (**BAR0** and **BAR1**, offsets 10h and 14h, respectively). After the PEX 8609 NT Port Link Interface Memory-Mapped register Base address is Set, the PEX 8609 Configuration Space registers are accessed, using Memory Reads and Writes to the 4-KB range, starting at offset 64 KB (1\_0000h, Virtual Interface) and offset 68 KB (1\_1000h, Link Interface).

Figure 17-1. NT Mode Configuration Register Mapping to Memory-Mapped BAR

### 17.3.3 Device-Specific Cursor Mechanism

The Device-Specific Cursor mechanism is provided for use in development systems that can only generate *PCI r3.0* Configuration cycles (*that is*, the system cannot use either the [Device-Specific Memory-Mapped Configuration Mechanism](#), nor generate Extended Configuration Requests to access the Extended Configuration Space).

In [Figure 17-2](#), the software uses the **Configuration Address Window** (CFGADDR) register (offset **F8h**) to select the NT Port Link or Virtual Interface Configuration Space registers, including the PCI Express Extended Configuration Space registers (offsets 100h through FFFh).

Software uses the **Configuration Data Window** (CFGDATA) register (offset **FCh**) to write to or read from the selected Configuration Space registers.

Refer to [Section 17.10](#), “NT Port Link Interface Vendor-Specific Capability 3 Registers (Offsets C8h – FCh),” for the register descriptions.

**Figure 17-2. Configuration Space View**

## 17.4 Register Descriptions

The remainder of this chapter details the PEX 8609 NT Port Link Interface registers, including:

- Bit/field names
- Description of register functions in the PEX 8609 NT Port Link and Virtual Interfaces
- Type (*such as* RW or HwInit; refer to [Table 14-5](#), “Register Types, Grouped by User Accessibility,” for Type descriptions)
- Whether the power-on/reset value can be modified, by way of the PEX 8609 serial EEPROM and/or I<sup>2</sup>C/SMBus Initialization feature
- Default power-on/reset value

## 17.5 NT Port Link Interface PCI-Compatible Type 0 Configuration Header Registers (Offsets 00h – 3Ch)

This section details the NT Port Link Interface PCI-Compatible Type 0 Configuration Header registers. [Table 17-2](#) defines the register map.

**Table 17-2. NT Port Link Interface PCI-Compatible Type 0 Configuration Header Register Map**

## 17.8 NT Port Link Interface PCI Express Capability Registers (Offsets 68h – A0h)

The registers detailed in [Section 14.9, “PCI Express Capability Registers \(Offsets 68h – A0h\),”](#) are also applicable to the NT Port Link Interface, except as defined in [Table 17-5](#) (register map; offsets 7Ch, 80h, and 90h are **reserved**), and [Register 17-20](#) through [Register 17-25](#).

## 17.9 NT Port Link Interface Subsystem ID and Subsystem Vendor ID Capability Registers (Offsets A4h – C4h)

The registers detailed in [Section 14.10, “Subsystem ID and Subsystem Vendor ID Capability Registers \(Offsets A4h – FCh\),”](#) are also applicable to the NT Port, except as defined in [Table 17-6](#) (register map) and [Register 17-26](#).

**Table 17-6. NT Port Link Interface Subsystem ID and Subsystem Vendor ID Capability Register Map**

## 17.10 NT Port Link Interface Vendor-Specific Capability 3 Registers (Offsets C8h – FCh)

This section details the NT Port Link Interface Vendor-Specific Extended Capability 3 registers. [Table 17-7](#) defines the register map used by the NT Port.

The Cursor Mechanism registers at offsets [F8h](#) and [FCh](#) provide a means for accessing PCI Express Extended Configuration Space registers (offsets 100h through FFFh) within the NT Port Link and Virtual Interfaces, when only standard PCI Configuration transactions (that do not support the *Extended Register Number* field within the Completion Request Header) are available.

**Table 17-7. NT Port Link Interface Vendor-Specific Extended Capability 3 Register Map**

## 17.14 NT Port Link Interface Device-Specific Registers (Offsets 1C0h – C88h)

The registers detailed in [Section 14.14, “Device-Specific Registers \(Offsets 1C0h – 51Ch\)”](#), and [Section 14.16, “Device-Specific Registers \(Offsets 530h – F8Ch\)”](#) (for offsets A00h through C88h), are unique to the PEX 8609 and not referenced in the *PCI Express Base r2.0*. These registers are also applicable to the NT Port Link Interface, except as defined in [Table 17-11](#) (register map; offsets 200h through 57Ch, 680h through 94Ch, and 964h through C30h, are **reserved**, and offset 960h is associated with an NT Port Link Interface-specific register) through [Table 17-16](#), and [Register 17-37](#) through [Register 17-45](#).

Another NT Port Link Interface Device-Specific register is detailed in [Section 17.16, “NT Port Link Interface Device-Specific Registers – Source Queue Weight \(Offsets F00h – F3Ch\).”](#)

**Note:** It is recommended that these registers not be changed from their default values.

**Table 17-11. NT Port Link Interface Device-Specific Register Map**

|                                                                                                                |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |                                       |  |  |  |                                              |  |  |  |  |  |  |  |  |  |  |  |        |

### 17.14.1 NT Port Link Interface Device-Specific Registers – Error Checking and Debug (Offsets 1C0h – 1FCh)

The registers detailed in [Section 14.14.1, “Device-Specific Registers – Error Checking and Debug \(Offsets 1C0h – 1FCh\)”](#), are also applicable to the NT Port Link Interface, except as defined in [Table 17-12](#) (register map; offsets 1C0h, 1C4h, 1CCh through 1DCh, and 1F4h are **reserved**), and [Register 17-37](#) through [Register 17-39](#).

### 17.14.3 NT Port Link Interface Device-Specific Registers – Vendor-Specific Extended Capability 2 (Offsets 950h – 95Ch)

The registers detailed in [Section 14.16.10, “Device-Specific Registers – Vendor-Specific Extended Capability 2 \(Offsets 950h – 95Ch\),”](#) are also applicable to the NT Port, except for the Next Capability Offset value, as defined in [Table 17-14](#) (register map) and [Register 17-40](#).

**Table 17-14. NT Port Link Interface Device-Specific, Vendor-Specific Extended Capability 2 Register Map**

### 17.15.1 NT Port Link Interface Bridging-Specific Registers – Requester ID Translation Lookup Table Entry (Addresses DB4h – DF0h)

This section describes the NT Port Link Interface NT Bridging-Specific Requester ID Translation Lookup Table (LUT) Entry registers. The NT Port uses these registers for Requester ID translation when it forwards:

- Memory Requests from the NT Port Link Interface to the NT Port Virtual Interface, –or–
- Completion TLPs from the NT Port Virtual Interface to the NT Port Link Interface

If the application needs to send traffic through the NT Port Link Interface, program the registers listed in this group with the corresponding Requester's Requester ID, then Set the *LUT Entry\_n Enable* and *LUT Entry\_m Enable* bits (bits 0 and 16, respectively) for each LUT entry, as needed.

Table 17-18 defines the register and address locations, as they relate to [Register 17-46](#).

**Table 17-18. NT Port Link Interface NT Bridging-Specific Requester ID Translation LUT Entry\_n\_m Register Locations**

| ADDR Location | Lookup Table Entry_n_m | ADDR Location | Lookup Table Entry_n_m |
|---------------|------------------------|---------------|------------------------|

| 1      | <b>LUT Entry<sub>n</sub> No Snoop Enable</b><br>If Set, the NT Port Clears the TLP <i>No Snoop</i> attribute bit for the Memory Request, then goes from the NT Port Link Interface to the NT Port Virtual Interface, and re-calculates the ECRC. If the original TLP has an ECRC error, the NT Port corrupts the re-calculated ECRC before transmitting to the other Host domain. The NT Port sets the <i>No Snoop</i> attribute bit when it forwards the Completion TLP from the NT Port Virtual Interface to the NT Port Link Interface if this bit is Set for the corresponding Requester ID entry. This ECRC rule applies to Completion TLPs as well.<br><br>0 = Disables<br>1 = Enables    |                                                                         | RW    | Yes                                | 0       |

| 17     | <b>LUT Entry<sub>m</sub> No Snoop Enable</b><br>If Set, the NT Port Clears the TLP <i>No Snoop</i> attribute bit for the Memory Request, then goes from the NT Port Link Interface to the NT Port Virtual Interface, and re-calculates the ECRC. If the original TLP has an ECRC error, the NT Port corrupts the re-calculated ECRC before transmitting to the other Host domain. The NT Port sets the <i>No Snoop</i> attribute bit when it forwards the Completion TLP from the NT Port Virtual Interface to the NT Link Virtual Interface if this bit is Set for the corresponding Requester ID entry. This ECRC rule applies to Completion TLPs as well.<br><br>0 = Disables<br>1 = Enables |                                                                         | RW    | Yes                                | 0       |

17.16 NT Port Link Interface Device-Specific Registers – Source Queue Weight (Offsets F00h – F3Ch)

Register offset [F10h](#), detailed in [Section 14.16.17, “Device-Specific Registers – Source Queue Weight and Soft Error \(Offsets F00h – F3Ch\),”](#) is also applicable to the NT Port Link Interface. The remaining registers within the register set are **reserved** in the NT Port Link Interface, as defined in the [Table 17-19](#) register map.

Other NT Port Link Interface Device-Specific registers are detailed in [Section 17.14, “NT Port Link Interface Device-Specific Registers \(Offsets 1C0h – C88h\).”](#)

## 17.17 NT Port Link Interface Advanced Error Reporting Extended Capability Registers (Offsets FB4h – FDCh)

The registers detailed in [Section 14.17, “Advanced Error Reporting Extended Capability Registers \(Offsets FB4h – FDCh\),”](#) are also applicable to the NT Port Link Interface, except as defined in [Table 17-20](#) (register map), [Register 17-47](#), and the exceptions indicated in the note.

**Notes:** Data Link Protocol and Surprise Down PCI Express errors are not valid for the NT Port Link nor Virtual Interfaces, and therefore do not affect register offsets FB8h, FBCh, and FC0h in NT mode.

*Receiver, Bad TLP, Bad DLLP, Replay Number Rollover, and Replay Timer Timeout*  
PCI Express errors are not valid for the NT Port Link nor Virtual Interfaces, and therefore do not affect register offsets FC4h and FC8h in NT mode.

## Chapter 18 DMA Interface Registers – DMA Mode Only

### 18.1 Introduction

This chapter defines the PEX 8609 DMA Interface registers when the PEX 8609 is operating in DMA mode. Other registers are defined in:

- [Chapter 14, “Transparent Port Registers”](#)
- [Chapter 16, “NT Port Virtual Interface Registers – NT Mode Only”](#)
- [Chapter 17, “NT Port Link Interface Registers – NT Mode Only”](#)

All PEX 8609 registers can be accessed by Configuration or Memory Requests.

For further details regarding register names and descriptions, refer to the following specifications:

- *PCI r3.0*
- *PCI Power Mgmt. r1.2*
- *PCI Express Base r2.0*

## 18.2 DMA Interface Type 0 Register Map

Table 18-1 defines the DMA Interface Type 0 register mapping.

**Table 18-1. DMA Interface Type 0 Register Map  
(DMA of Upstream Port)**

|                                                                                             |  |  |  |  |  |  |  |    |  |  |  |                                            |  |  |  |                                       |  |  |  |  |  |  |  |                                |  |  |  |  |  |  |  |        |      |

## 18.3 Register Access

The PEX 8609 DMA (Upstream Port, Function 1) implements a 4-KB Configuration Space. The lower 256 bytes (offsets 00h through FFh) comprise the PCI-compatible Configuration Space, and the upper 960 Dwords (offsets 100h through FFFh) comprise the PCI Express Extended Configuration Space. The PEX 8609 supports two mechanisms for accessing DMA Interface registers:

- [PCI Express Base r2.0 Configuration Mechanism](#)
- [Device-Specific Memory-Mapped Configuration Mechanism](#)

### 18.3.1 PCI Express Base r2.0 Configuration Mechanism

The *PCI Express Base r2.0* mechanism is divided into two mechanisms:

- [PCI r3.0-Compatible Configuration Mechanism](#) – Provides Conventional PCI access to the first 256 bytes (the bytes at offsets 00h through FFh) of the DMA Interface Configuration register space
- [PCI Express Enhanced Configuration Access Mechanism](#) – Provides access to the entire 4-KB Configuration Space

#### 18.3.1.1 PCI r3.0-Compatible Configuration Mechanism

***Do not use this mechanism to access the PEX 8609 Device-Specific Configuration registers.***

The *PCI r3.0-Compatible* Configuration mechanism provides standard access to the PEX 8609 DMA Interface's first 256 bytes (the bytes at offsets 00h through FFh) of the PCI Express Configuration Space.

This mechanism is used to access the following PEX 8609 DMA Interface Type 0 (PCI endpoint) registers:

- [DMA Interface PCI-Compatible Type 0 Configuration Header Registers \(Offsets 00h – 3Ch\)](#)
- [DMA Interface PCI Power Management Capability Registers \(Offsets 40h – 44h\)](#)
- [DMA Interface MSI Capability Registers \(Offsets 48h – 64h\)](#)
- [DMA Interface PCI Express Capability Registers \(Offsets 68h – A0h\)](#)
- [DMA Interface Subsystem ID and Subsystem Vendor ID Capability Registers \(Offsets A4h – C4h\)](#)

The *PCI r3.0-Compatible* Configuration mechanism uses PCI Type 0 Configuration transactions to access the PEX 8609 Configuration registers.

The PEX 8609 DMA Interface registers can be accessed from the upstream Port by Type 0 Configuration. A PEX 8609 DMA-enabled device decodes all Type 0 Configuration accesses received on its upstream Port for DMA Interface access, when any of the following conditions exist:

- If the specified Bus Number and Device Number that matches the upstream Port and Function Number specified in Configuration accesses is 1.
- If the specified Bus Number and Device Number that matches the upstream Port and Function Number specified in Configuration accesses is 1, but the register address is invalid, the PEX 8609 responds with an Unsupported Request (UR). The *Completer ID* field for Non-Posted accesses will match DMA's Bus Number, Device Number, and Function Number.
- If the specified Bus Number and Device Number that matches the upstream Port and Function Number specified in Configuration accesses is 1, but the *EP* bit is Set, the PEX 8609 responds with a UR. The *Completer ID* field for Non-Posted accesses will match DMA's Bus Number, Device Number, and Function Number.

Because the mechanism is limited to the first 256 bytes of the DMA Interface Configuration register space, the [PCI Express Enhanced Configuration Access Mechanism](#) or [Device-Specific Memory-Mapped Configuration Mechanism](#) must be used to access beyond Byte FFh.

This mechanism uses the same Request format as the [PCI Express Enhanced Configuration Access Mechanism](#). For PCI-compatible Configuration Requests, the *Extended Register Address* field must be all zeros (0).

### 18.3.1.2 PCI Express Enhanced Configuration Access Mechanism

The PCI Express Enhanced Configuration mechanism uses a flat, Root Complex Memory-Mapped Address space to access the device Configuration registers. In this case, the Memory address determines the Configuration register accessed, and the Memory data returns the addressed register's contents. The Root Complex converts the Memory transaction into a Configuration transaction.

This mechanism can be used to access all PEX 8609 Configuration registers.

18.3.2 Device-Specific Memory-Mapped Configuration Mechanism

The Device-Specific Memory-Mapped Configuration mechanism provides a method to access the PEX 8609 DMA Interface Configuration Space, using Memory Read/Write transactions.

To use this mechanism, use the [PCI r3.0-Compatible Configuration Mechanism](#) to program the PEX 8609 DMA Interface **Base Address 0 DMA** and **Base Address 1 DMA** registers (**BAR0** and **BAR1**, offsets **10h** and **14h**, respectively). The DMA **BAR0/1** window size is 128 KB, out of which the first 4 KB is for PCI Express Configuration Space, and the next 4 KB, are mapped to Descriptor RAM, as illustrated in [Figure 18-1](#). Descriptor RAM is 256 bytes deep by 16 bytes wide, and can be initialized by Memory-Mapped access to **BAR0/1** at offsets 4 KB to 8 KB. This mapping allows users to randomly access each Descriptor.

After the PEX 8609 DMA Interface Memory-Mapped register Base address is Set, the PEX 8609 Configuration Space/Device-Specific Space registers can be accessed, using Memory Reads and Writes.

***Note:** DMA Address space is not included within the upstream Port, although it is orthogonal to Upstream Port Address space, as illustrated in [Figure 18-2](#).*

## 18.4 Register Descriptions

The remainder of this chapter details the PEX 8609 DMA Interface registers, including:

- Bit/field names
- Description of register functions in DMA mode
- Type (*such as* RW or HwInit; refer to [Table 14-5, “Register Types, Grouped by User Accessibility,”](#) for Type descriptions)
- Whether the power-on/reset value can be modified, by way of the PEX 8609 serial EEPROM and/or I<sup>2</sup>C/SMBus Initialization feature
- Default power-on/reset value

## 18.5 DMA Interface PCI-Compatible Type 0 Configuration Header Registers (Offsets 00h – 3Ch)

This section details the PCI-Compatible Type 0 Configuration Header registers in DMA mode. [Table 18-2](#) defines the register map.

**Table 18-2. DMA Interface PCI-Compatible Type 0 Configuration Header Register Map (DMA of Upstream Port)**

- a. Because the PEX 8609 does not consume auxiliary power, this bit is not sticky, and is always Cleared at power-on reset.
- b. With no serial EEPROM nor previous I<sup>2</sup>C programming, Reads return 00h for the **Data** and **Data Scale** registers (for all *Data Selects*).

# 18.7 DMA Interface MSI Capability Registers (Offsets 48h – 64h)

This section details the Message Signaled Interrupt (MSI) Capability registers in DMA mode. [Table 18-4](#) defines the register map.

**Table 18-4. DMA Interface MSI Capability Register Map (DMA of Upstream Port)<sup>a</sup>**

## 18.8 DMA Interface PCI Express Capability Registers (Offsets 68h – A0h)

This section details the PCI Express Capability registers in DMA mode. [Table 18-5](#) defines the register map.

**Table 18-5. DMA Interface PCI Express Capability Register Map (DMA of Upstream Port)**

|                            |                         |                               |                     |                |           |
|----------------------------|-------------------------|-------------------------------|---------------------|----------------|-----------|

### Register 18-30. 100h Device Serial Number Extended Capability Header (DMA of Upstream Port)

| Bit(s) | Description                                                                                                                   | Type | Serial EEPROM and I <sup>2</sup> C | Default |
|--------|-------------------------------------------------------------------------------------------------------------------------------|------|------------------------------------|---------|
| 15:0   | <b>PCI Express Extended Capability ID</b><br>Program to 0003h, as required by the <i>PCI Express Base r2.0</i> .              | RO   | Yes                                | 0003h   |
| 19:16  | <b>Capability Version</b><br>Program to 1h, as required by the <i>PCI Express Base r2.0</i> .                                 | RO   | Yes                                | 1h      |
| 31:20  | <b>Next Capability Offset</b><br>Program to FB4h, which is the <b>Advanced Error Reporting Extended Capability</b> structure. | RO   | Yes                                | FB4h    |

**Register 18-31. 104h Serial Number (Lower DW)**  
**(DMA of Upstream Port)**

| Bit(s) | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Type | Serial EEPROM and I <sup>2</sup> C | Default    |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|------------------------------------|------------|
| 31:0   | <b>PCI Express Device Serial Number (1st DW)</b><br>Lower half of a 64-bit register. Value Set by Serial EEPROM register initialization. Per the <i>PCI Express Base r2.0</i> , all switch Ports must contain the same value.<br>The Serial Number registers contain the IEEE-defined 64-bit Extended Unique Identifier (EUI-64™). The lower 24 bits are the Company ID value assigned by the IEEE registration authority, and the upper 40 bits are the Extension ID assigned by the identified Company. | RO   | Yes                                | B5DF_0E00h |

**Register 18-32. 108h Serial Number (Upper DW)**  
**(DMA of Upstream Port)**

| Bit(s) | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Type | Serial EEPROM and I <sup>2</sup> C | Default     |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|------------------------------------|-------------|
| 31:0   | <b>PCI Express Device Serial Number (2nd DW)</b><br>Upper half of a 64-bit register. Value Set by Serial EEPROM register initialization. Per the <i>PCI Express Base r2.0</i> , all switch Ports must contain the same value.<br>The Serial Number registers contain the IEEE-defined 64-bit Extended Unique Identifier (EUI-64™). The lower 24 bits are the Company ID value assigned by the IEEE registration authority, and the upper 40 bits are the Extension ID assigned by the identified Company. | RO   | Yes                                | BA_8601_10h |

## 18.12 Vendor-Specific Extended Capability Registers – DMA Channel (Offsets 1F4h – 5FCh)

This section details the Vendor-Specific Extended Capability DMA Channel registers in DMA mode. [Table 18-10](#) defines the register map.

**Table 18-10. DMA Interface Vendor-Specific Extended Capability DMA Channel Register Map (DMA of Upstream Port)**

|                                                      |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |                                       |  |  |  |                                            |  |  |  |                                      |  |  |  |  |  |  |  |        |      |  |  |      |

| 31:0   | <b>DMA Channel 0 Source Address Lower</b><br>Lower 32 bits of Source address where DMA Transfer Read starts. | RW   | Yes                                | 0000_0000h |

**Register 18-37. 204h DMA Channel 0 Source Address Upper (DMA of Upstream Port)**

| Bit(s) | Description                                                                                                  | Type | Serial EEPROM and I <sup>2</sup> C | Default    |
|--------|--------------------------------------------------------------------------------------------------------------|------|------------------------------------|------------|
| 31:0   | <b>DMA Channel 0 Source Address Upper</b><br>Upper 32 bits of Source address where DMA Transfer Read starts. | RW   | Yes                                | 0000_0000h |

**Register 18-38. 208h DMA Channel 0 Destination Address Lower (DMA of Upstream Port)**

| Bit(s) | Description                                                                                                                                           | Type  | Serial EEPROM and I <sup>2</sup> C | Default |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------|-------|------------------------------------|---------|
| 1:0    | <i>Reserved</i><br>Value is always the same as the lower two bits of the <b>DMA Channel 0 Source Address Lower</b> register (offset 200h[1:0]).       | RsvdP | No                                 | 00b     |
| 31:2   | <b>DMA Channel 0 Destination Address Lower</b><br>Lower 32 bits (including field [1:0] value) of Destination address where DMA Transfer Write starts. | RW    | Yes                                | 0-0h    |

**Register 18-39. 20Ch DMA Channel 0 Destination Address Upper (DMA of Upstream Port)**

| Bit(s) | Description                                                                                                             | Type | Serial EEPROM and I <sup>2</sup> C | Default    |
|--------|-------------------------------------------------------------------------------------------------------------------------|------|------------------------------------|------------|
| 31:0   | <b>DMA Channel 0 Destination Address Upper</b><br>Upper 32 bits of Destination address where DMA Transfer Write starts. | RW   | Yes                                | 0000_0000h |

**Register 18-40. 210h DMA Channel 0 Transfer Size (DMA of Upstream Port)**

| Bit(s) | Description                                                                                                       | Type  | Serial EEPROM and I <sup>2</sup> C | Default |
|--------|-------------------------------------------------------------------------------------------------------------------|-------|------------------------------------|---------|
| 26:0   | <b>DMA Channel 0 Transfer Size (Bytes)</b><br>Indicates the quantity of bytes to transfer during a DMA operation. | RW    | Yes                                | 0-0h    |
| 27     | <i>Reserved</i>                                                                                                   | RsvdP | No                                 | 0       |
| 28     | <b>DMA Channel 0 Destination Address Constant</b>                                                                 | RW    | Yes                                | 0       |
| 29     | <b>DMA Channel 0 Source Address Constant</b>                                                                      | RW    | Yes                                | 0       |
| 30     | <b>DMA Channel 0 DMA Done Interrupt Enable</b>                                                                    | RW    | Yes                                | 0       |
| 31     | <b>DMA Channel 0 DMA Valid</b>                                                                                    | RW    | Yes                                | 0       |

**Register 18-41. 214h DMA Channel 0 Descriptor Ring Address Lower (DMA of Upstream Port)**

| Bit(s) | Description                                                                                                                                                                                                | Type  | Serial EEPROM and I <sup>2</sup> C | Default |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|------------------------------------|---------|
| 5:0    | <i>Reserved</i>                                                                                                                                                                                            | RsvdP | No                                 | 0h      |
| 31:6   | <b>DMA Channel 0 Descriptor Ring Address Lower</b><br>Lower 32 bits of Descriptor Ring Base address where DMA Descriptor Read starts. Ensures 64-bit alignment.<br><i>Note: Bits [5:0] are always 00h.</i> | RW    | Yes                                | 0-0h    |

**Register 18-42. 218h DMA Channel 0 Descriptor Ring Address Upper (DMA of Upstream Port)**

| Bit(s) | Description                                                                                                                           | Type | Serial EEPROM and I <sup>2</sup> C | Default    |
|--------|---------------------------------------------------------------------------------------------------------------------------------------|------|------------------------------------|------------|
| 31:0   | <b>DMA Channel 0 Descriptor Ring Address Upper</b><br>Upper 32 bits of Descriptor Ring Base address where DMA Descriptor Read starts. | RW   | Yes                                | 0000_0000h |

**Register 18-43. 21Ch DMA Channel 0 Next Descriptor Ring Address Lower (DMA of Upstream Port)**

| Bit(s) | Description                                                                                                                                                | Type  | Serial EEPROM and I <sup>2</sup> C | Default   |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|------------------------------------|-----------|
| 3:0    | <i>Reserved</i>                                                                                                                                            | RsvdP | No                                 | 0h        |
| 31:4   | <b>DMA Channel 0 Next Descriptor Ring Address Lower</b><br>Lower 32 bits (including field [3:0] value) of Descriptor Ring Base address of next Descriptor. | RW    | Yes                                | 0000_000h |

**Register 18-44. 220h DMA Channel 0 Descriptor Ring Size  
(DMA of Upstream Port)**

| Bit(s) | Description                                                                                                                                                                                                                                                                                                                                                                                                                         | Type | Serial EEPROM and I <sup>2</sup> C | Default    |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|------------------------------------|------------|
| 31:0   | <b>DMA Channel 0 Descriptor Ring Size</b><br>Indicates the quantity of Descriptors in the ring. The value includes both Normal Descriptor and Extended Descriptor formats.<br>The ring must be greater than or equal to (Prefetch Limit Size + Depth of Descriptor FIFO + 1), to avoid the possibility of the Descriptor prefetching looparound faster than the Completion Status writeback for that Descriptor in Ring Delay mode. | RW   | Yes                                | 0000_0000h |

**Register 18-45. 224h DMA Channel 0 Last Descriptor Address Lower  
(DMA of Upstream Port)**

| Bit(s) | Description                                                                                                                                                                                                                       | Type  | Serial EEPROM and I <sup>2</sup> C | Default   |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|------------------------------------|-----------|
| 3:0    | <i>Reserved</i>                                                                                                                                                                                                                   | RsvdP | No                                 | 0h        |
| 31:4   | <b>DMA Channel 0 Last Descriptor Address Lower</b><br>Lower 32 bits (including field [3:0] value) of the last Descriptor address. Software polls this register to determine the Descriptor progress for the current DMA transfer. | RO    | Yes                                | 0000_000h |

**Register 18-46. 228h DMA Channel 0 Last Descriptor Transfer Size  
(DMA of Upstream Port)**

| Bit(s) | Description                                                                                                                                       | Type  | Serial EEPROM and I <sup>2</sup> C | Default |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------|-------|------------------------------------|---------|
| 26:0   | <b>DMA Channel 0 Last Descriptor Transfer Size</b><br>Last Descriptor's Transfer size, which corresponds to the last Descriptor Address register. | RO    | Yes                                | 0-0h    |
| 31:27  | <i>Reserved</i>                                                                                                                                   | RsvdP | No                                 | 0-0h    |

**Register 18-47. 22Ch DMA Channel 0 Bandwidth  
(DMA of Upstream Port)**

| Bit(s) | Description                                                                                                                                                                    | Type  | Serial EEPROM and I <sup>2</sup> C | Default |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|------------------------------------|---------|
| 15:0   | <b>DMA Channel 0 DMA Clocks to Transfer</b><br>Defines the wait period, in 4-ns clock increments, for intervals between two Memory Read Requests issued by the DMA Controller. | RW    | Yes                                | 0000h   |
| 16     | <b>DMA Channel 0 DMA Immediate Pause</b>                                                                                                                                       | RW    | Yes                                | 0       |
| 31:17  | <i>Reserved</i>                                                                                                                                                                | RsvdP | No                                 | 0-0h    |

**Register 18-48. 234h DMA Channel 0 Maximum Prefetch Limit (DMA of Upstream Port)**

| Bit(s) | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | Type  | Serial EEPROM and I <sup>2</sup> C | Default  |

**Register 18-58. 304h DMA Channel 1 Source Address Upper (DMA of Upstream Port)**

| Bit(s) | Description                                                                                                  | Type | Serial EEPROM and I <sup>2</sup> C | Default    |
|--------|--------------------------------------------------------------------------------------------------------------|------|------------------------------------|------------|
| 31:0   | <b>DMA Channel 1 Source Address Upper</b><br>Upper 32 bits of Source address where DMA Transfer Read starts. | RW   | Yes                                | 0000_0000h |

**Register 18-59. 308h DMA Channel 1 Destination Address Lower (DMA of Upstream Port)**

| Bit(s) | Description                                                                                                                                           | Type  | Serial EEPROM and I <sup>2</sup> C | Default |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------|-------|------------------------------------|---------|
| 1:0    | <b>Reserved</b><br>Value is always the same as the lower two bits of the <b>DMA Channel 1 Source Address Lower</b> register (offset 300h[1:0]).       | RsvdP | No                                 | 00b     |
| 31:2   | <b>DMA Channel 1 Destination Address Lower</b><br>Lower 32 bits (including field [1:0] value) of Destination address where DMA Transfer Write starts. | RW    | Yes                                | 0-0h    |

**Register 18-60. 30Ch DMA Channel 1 Destination Address Upper (DMA of Upstream Port)**

| Bit(s) | Description                                                                                                             | Type | Serial EEPROM and I <sup>2</sup> C | Default    |
|--------|-------------------------------------------------------------------------------------------------------------------------|------|------------------------------------|------------|
| 31:0   | <b>DMA Channel 1 Destination Address Upper</b><br>Upper 32 bits of Destination address where DMA Transfer Write starts. | RW   | Yes                                | 0000_0000h |

**Register 18-61. 310h DMA Channel 1 Transfer Size  
(DMA of Upstream Port)**

| Bit(s) | Description                                                                                                       | Type  | Serial<br>EEPROM<br>and I <sup>2</sup> C | Default |
|--------|-------------------------------------------------------------------------------------------------------------------|-------|------------------------------------------|---------|
| 26:0   | <b>DMA Channel 1 Transfer Size (Bytes)</b><br>Indicates the quantity of bytes to transfer during a DMA operation. | RW    | Yes                                      | 0-0h    |
| 27     | <i>Reserved</i>                                                                                                   | RsvdP | No                                       | 0       |
| 28     | <b>DMA Channel 1 Destination Address Constant</b>                                                                 | RW    | Yes                                      | 0       |
| 29     | <b>DMA Channel 1 Source Address Constant</b>                                                                      | RW    | Yes                                      | 0       |
| 30     | <b>DMA Channel 1 DMA Done Interrupt Enable</b>                                                                    | RW    | Yes                                      | 0       |
| 31     | <b>DMA Channel 1 DMA Valid</b>                                                                                    | RW    | Yes                                      | 0       |

**Register 18-62. 314h DMA Channel 1 Descriptor Ring Address Lower  
(DMA of Upstream Port)**

| Bit(s) | Description                                                                                                                                                                                                | Type  | Serial<br>EEPROM<br>and I <sup>2</sup> C | Default |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|------------------------------------------|---------|
| 5:0    | <i>Reserved</i>                                                                                                                                                                                            | RsvdP | No                                       | 00h     |
| 31:6   | <b>DMA Channel 1 Descriptor Ring Address Lower</b><br>Lower 32 bits of Descriptor Ring Base address where DMA Descriptor Read starts. Ensures 64-bit alignment.<br><i>Note: Bits [5:0] are always 00h.</i> | RW    | Yes                                      | 0-0h    |

**Register 18-63. 318h DMA Channel 1 Descriptor Ring Address Upper  
(DMA of Upstream Port)**

| Bit(s) | Description                                                                                                                           | Type | Serial<br>EEPROM<br>and I <sup>2</sup> C | Default    |
|--------|---------------------------------------------------------------------------------------------------------------------------------------|------|------------------------------------------|------------|
| 31:0   | <b>DMA Channel 1 Descriptor Ring Address Upper</b><br>Upper 32 bits of Descriptor Ring Base address where DMA Descriptor Read starts. | RW   | Yes                                      | 0000_0000h |

**Register 18-64. 31Ch DMA Channel 1 Next Descriptor Ring Address Lower  
(DMA of Upstream Port)**

| Bit(s) | Description                                                                                                                                                | Type  | Serial<br>EEPROM<br>and I <sup>2</sup> C | Default   |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|------------------------------------------|-----------|
| 3:0    | <i>Reserved</i>                                                                                                                                            | RsvdP | No                                       | 0h        |
| 31:4   | <b>DMA Channel 1 Next Descriptor Ring Address Lower</b><br>Lower 32 bits (including field [3:0] value) of Descriptor Ring Base address of next Descriptor. | RW    | Yes                                      | 0000_000h |

**Register 18-65. 320h DMA Channel 1 Descriptor Ring Size (DMA of Upstream Port)**

| Bit(s) | Description                                                                                                                                                                                                                                                                                                                                                                                                                         | Type | Serial EEPROM and I <sup>2</sup> C | Default    |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|------------------------------------|------------|
| 31:0   | <b>DMA Channel 1 Descriptor Ring Size</b><br>Indicates the quantity of Descriptors in the ring. The value includes both Normal Descriptor and Extended Descriptor formats.<br>The ring must be greater than or equal to (Prefetch Limit Size + Depth of Descriptor FIFO + 1), to avoid the possibility of the Descriptor prefetching looparound faster than the Completion Status writeback for that Descriptor in Ring Delay mode. | RW   | Yes                                | 0000_0000h |

**Register 18-66. 324h DMA Channel 1 Last Descriptor Address Lower (DMA of Upstream Port)**

| Bit(s) | Description                                                                                                                                                                                                                       | Type  | Serial EEPROM and I <sup>2</sup> C | Default   |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|------------------------------------|-----------|
| 3:0    | <b>Reserved</b>                                                                                                                                                                                                                   | RsvdP | No                                 | 0h        |
| 31:4   | <b>DMA Channel 1 Last Descriptor Address Lower</b><br>Lower 32 bits (including field [3:0] value) of the last Descriptor address. Software polls this register to determine the Descriptor progress for the current DMA transfer. | RO    | Yes                                | 0000_000h |

**Register 18-67. 328h DMA Channel 1 Last Descriptor Transfer Size (DMA of Upstream Port)**

| Bit(s) | Description                                                                                                                                       | Type  | Serial EEPROM and I <sup>2</sup> C | Default |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------|-------|------------------------------------|---------|
| 26:0   | <b>DMA Channel 1 Last Descriptor Transfer Size</b><br>Last Descriptor's Transfer size, which corresponds to the last Descriptor Address register. | RO    | Yes                                | 0-0h    |
| 31:27  | <b>Reserved</b>                                                                                                                                   | RsvdP | No                                 | 0-0h    |

**Register 18-68. 32Ch DMA Channel 1 Bandwidth (DMA of Upstream Port)**

| Bit(s) | Description                                                                                                                                                                    | Type  | Serial EEPROM and I <sup>2</sup> C | Default |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|------------------------------------|---------|
| 15:0   | <b>DMA Channel 1 DMA Clocks to Transfer</b><br>Defines the wait period, in 4-ns clock increments, for intervals between two Memory Read Requests issued by the DMA Controller. | RW    | Yes                                | 0000h   |
| 16     | <b>DMA Channel 1 DMA Immediate Pause</b>                                                                                                                                       | RW    | Yes                                | 0       |
| 31:17  | <b>Reserved</b>                                                                                                                                                                | RsvdP | No                                 | 0-0h    |

**Register 18-69. 334h DMA Channel 1 Maximum Prefetch Limit  
(DMA of Upstream Port)**

| Bit(s) | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | Type  | Serial<br>EEPROM<br>and I <sup>2</sup> C | Default  |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|------------------------------------------|----------|
| 7:0    | <b>DMA Channel 1 Maximum Prefetch Limit</b><br>Indicates the maximum quantity of Descriptors that can be prefetched for this channel.<br>A value of 0 = 256 in One-Channel mode, when this limit is reached, DMA Descriptor prefetching stops, and resumes only after the value drops below the limit, to an integer multiple of 4 value.<br>For a value of 1, only one Descriptor is prefetched. When that one Descriptor is active, a second Descriptor is prefetched.<br>For a value of 4, four Descriptors are prefetched. When the fourth Descriptor is active, another four Descriptors are prefetched.<br>For values of 8, 12, 16, and so forth (up to FFh), when the count is 4 less than the Maximum Prefetch Limit, four more Descriptors are prefetched.<br><i>Note: The value can be programmed only with a multiple of 4 or 1.</i> | RW    | Yes                                      | 00h      |

**Register 18-111. 534h DMA Channel 3 Maximum Prefetch Limit  
(DMA of Upstream Port)**

| Bit(s) | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | Type  | Serial<br>EEPROM<br>and I <sup>2</sup> C | Default  |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|------------------------------------------|----------|
| 7:0    | <b>DMA Channel 3 Maximum Prefetch Limit</b><br>Indicates the maximum quantity of Descriptors that can be prefetched for this channel.<br>A value of 0 = 256 in One-Channel mode, when this limit is reached, DMA Descriptor prefetching stops, and resumes only after the value drops below the limit, to an integer multiple of 4 value.<br>For a value of 1, only one Descriptor is prefetched. When that one Descriptor is active, a second Descriptor is prefetched.<br>For a value of 4, four Descriptors are prefetched. When the fourth Descriptor is active, another four Descriptors are prefetched.<br>For values of 8, 12, 16, and so forth (up to FFh), when the count is 4 less than the Maximum Prefetch Limit, four more Descriptors are prefetched.<br><i>Note: The value can be programmed only with a multiple of 4 or 1.</i> | RW    | Yes                                      | 00h      |

## Chapter 19 Dual Clocking Support

### 19.1 Introduction

The Dual Clocking feature allows the PEX 8609 to be used in a Spread Spectrum Clocking (SSC) environment and communicate with devices that are operating in a Constant Frequency Clocking (CFC) environment. This capability is necessary for systems in which the upstream Port connects to the SSC source, while downstream Ports connect to Links running on CFC domains.

The SSC isolated Port does not have to be the upstream Port; however, it does need to be Port 0, because all the SSC resources are located in Port 0. Port 0 must be connected to an SSC domain, and the other Ports must be connected to a CFC domain, as illustrated in [Figure 19-1](#).

Most systems support SSC; however, the *PCI Express Base r2.0* specifies that REFCLKs of two interconnected devices must be within a  $\pm 300$  ppm frequency tolerance of one another.

The *PCI Express Base r2.0* specifies that the data rate of two connected Ports must be within  $\pm 300$  ppm from one another. The *PCI Express Base r2.0* also specifies that the data rate can be SSC modulation, which is defined as a  $\pm 0/-5,000$  ppm modulation from the base frequency. This essentially requires that if one device is using a SSC clock, then the other device must use the same clock, to be able to track the frequency modulation. Therefore, a device on a system that supports SSC clocking cannot be connected to a device on another system that does not use SSC. If a system supports SSC, all devices in the PCI Express interconnect must have the same Reference Clock source, to allow traffic to communicate between them. However, this is not practical in the case of chassis-to-chassis or blade-to-blade PCI Express traffic. If each chassis or blade has its own SSC source, special clock isolation circuitry is required to enable such configurations to communicate between themselves. For this reason, the PEX 8609 supports two REFCLK inputs that allow traffic to move from the SSC clock domain on the upstream Port to a CFC clock domain on the downstream Ports, thereby allowing two different chassis or blades to communicate with one another.

The SSC domain runs at a frequency between 99.5 and 100 MHz. The CFC domain runs at a frequency of 100 MHz. Because the SSC and CFC domain average frequencies are not identical, the PEX 8609 provides buffering and flow control to ensure that data does not overflow nor underflow as it passes from one clock domain to the other. Dual Clocking support is provided in fan-in/fan-out configurations when Port 0 is programmed to a x4 Link width.

Figure 19-1. PEX 8609 in a Dual Clock System

## 19.2 Dual Clocking Operation

Dual Clocking is enabled when the following conditions are met:

- [STRAP\\_SSC\\_ISO\\_ENABLE#](#) input is pulled or tied Low to [VSS](#) (GND)
- Port 0's Link width is x4

When Dual Clocking is enabled, the REFCLK balls are mapped as follows:

- [PEX\\_REFCLKn](#) and [PEX\\_REFCLKp](#) signal balls become the SSC domain Clock signals
- [PEX\\_REFCLK\\_CFCn](#) and [PEX\\_REFCLK\\_CFCp](#) signal balls become the CFC domain Clock signals

If the system design does not use Dual Clocking, the [STRAP\\_SSC\\_ISO\\_ENABLE#](#) input must be pulled or tied High to [VDD25](#), and the [PEX\\_REFCLK\\_CFCn](#) and [PEX\\_REFCLK\\_CFCp](#) signals must remain floating. If the PEX 8609 uses SSC on its upstream Port, or the upstream Port is not configured to Port 0, the [PEX\\_REFCLKn](#) and [PEX\\_REFCLKp](#) signals must be shared by all downstream devices. If the PEX 8609 uses a Constant Frequency source on its upstream Port, each downstream device can use an independent CFC REFCLK source, provided that it meets the *PCI Express Base r2.0*-defined PCI Express frequency tolerance of  $\pm 300$  ppm.

## Chapter 20 Test and Debug

### 20.1 Introduction

This chapter describes the following test- and debug-related information:

- [Physical Layer Loopback Operation](#)
- [User Test Pattern](#)
- [Pseudo-Random Bit Sequence](#)
- [Using the Even/Odd Port SerDes Quad x Diagnostic Data Registers](#)
- [Pseudo-Random and Bit-Pattern Generation](#)
- [PHY Testability Features](#)
- [JTAG Interface](#)
- [Lane Good Status LEDs](#)

## 20.2 Physical Layer Loopback Operation

### 20.2.1 Overview

Physical Layer (PHY) Loopback functions are used to test the SerDes in the PEX 8609, connections between devices, and SerDes of external devices, as well as various PEX 8609 and external digital logic. The PEX 8609 supports four types of Loopback operations, as described in [Table 20-1](#). Additional information regarding each type is provided in the sections that follow.

**Table 20-1. Loopback Operations**

| Operation                                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">Analog Loopback Master Mode</a>  | This mode depends upon an external device or passive connection ( <i>such as</i> a cable) to loopback the transmitted data to the PEX 8609, without SKIP Ordered-Set clock compensation. If an external device is used, it must not include its Elastic buffer in the Slave Loopback data path, so that SKIP Ordered-Sets are not inserted. A device's re-transmitted Receive data must be sent back to the Master, synchronous to the Master's Transmit Reference Clock. <i>That is</i> , the Slave device re-serializes the Transmit data, using the recovered clock from the received data. In that mode, the PRBS generator and checker should be used to create and check the data pattern.                                                                                                                                                                                                                                                                          |
| <a href="#">Digital Loopback Master Mode</a> | This mode depends upon an external device to loopback the transmitted data that includes at least its Elastic buffer in the Loopback data path, allowing for reliable loopback testing, in case the two devices have asynchronous Reference Clock sources with Parts per Million (PPM) offsets. The Master's pattern generator inserts SKIP Ordered-Sets at regular intervals, and its received data checker can handle PPM offset clock compensation, by way of SKIP symbol addition or deletion. The PEX 8609 provides a User Test Pattern generator and checker that can be used for Digital loopback testing.                                                                                                                                                                                                                                                                                                                                                         |
| <a href="#">Analog Loopback Slave Mode</a>   | The PEX 8609 enters this mode when an external device transmits Training Sets with the <i>Loopback Training Control Bit Set</i> and the <a href="#">Common Physical Layer Safety and Test</a> register <a href="#">Analog Loopback Enable</a> bit (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offset 23Ch[21]) is Set. Another way to unconditionally force the Slave into Analog loopback is described later in <a href="#">Section 20.2.4</a> .<br>While in this mode, the received data is looped back from the SerDes 10-bit Receive interface to the 10-bit Transmit interface. Internal to the SerDes, the serial-to-parallel and parallel-to-serial converters are included in the Loopback data path. The re-serialized data is transmitted back to the Master device synchronous to that Master's Reference Clock. This is because the recovered clock is fed back around to the Transmit interface and used as the Tx clock. |
| <a href="#">Digital Loopback Slave Mode</a>  | The PEX 8609 enters this mode when an external device transmits Training Sets with the <i>Loopback Training Control Bit Set</i> and the <a href="#">Common Physical Layer Safety and Test</a> register <a href="#">Analog Loopback Enable</a> bit (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offset 23Ch[21]) is Cleared. This is the default Loopback mode for the LTSSM Slave <i>Loopback.Active</i> state. In this mode, the data is looped back at the 8-bit level, which includes the PEX 8609's Elastic buffer, 8b/10b decoder, and 8b/10b encoder in the Slave Loopback data path. Asynchronous clock compensation can occur in the Elastic buffer through SKIP symbol addition or deletion, depending upon clock PPM offsets and fill threshold decoding. The Master data pattern checker must be able to handle the presence of SKIP Ordered-Sets and variations in their contents.                                          |

## 20.2.2 Analog Loopback Master Mode

Analog Loopback Master mode is typically used for Analog Far-End testing (refer to [Figure 20-1](#)), with a shallow Loopback path Slave device, to determine overall Bit Error rates. However, it can also be used for passive external serial loopback with a cable. Looping back with a cable includes the internal circuitry, package connections to bond pads, package balls, board traces, and any connectors that might be in the test data path, as illustrated in [Figure 20-2](#). A PRBS pattern is typically used for this mode, because it is appropriate for bit error rate testing. A User Test Pattern (UTP) is **not** recommended for this application – refer to [Section 20.3](#) for details.

Figure 20-1. Analog Far-End Loopback

Figure 20-2. Cable Loopback

### 20.2.2.1 Initiating Far-End Analog Operations in PEX 8609 Master Devices

**Note:** *Initiating a Master Loopback operation on an upstream Port can cause a Deadlock condition to occur, unless an I<sup>2</sup>C Slave interface is used to write and read Configuration Space register bits instead of writing them through upstream Port Configuration transactions. Therefore, it is recommended to restrict Analog Master loopback testing to downstream Ports when external devices are used.*

One way to test Master Analog loopback with passive cables is to have an upstream Port connected to a Root Complex, for Configuration Write/Read transactions that are used to Set and monitor the key device register bits. In that case, only downstream Ports would be test-capable, to avoid potential Deadlock conditions on the upstream Port. Alternatively, an I<sup>2</sup>C Slave interface and Rapid Development Kit (RDK) software could be used to write to or read from the registers. This makes any Port testable. The user has the option of attaching one or more cables to the appropriate high-speed Tx and Rx differential pairs that belong to the Ports being tested.

Loopback cables can be attached before or after a standard power-up initialization sequence. If the cables are attached before power-up, use a serial EEPROM to program the **Even/Odd Port Physical Layer Command/Status** register *Port x Loopback Command* bit (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port – Even Ports, offset 220h[16, 12, 8, 0], and Odd Ports, offset 224h[16, 12, 8, 0]) for the Port being tested. The Port's *Port x Loopback Command* bit arms the Port to enter the *Master Loopback.Entry* state. When written from a serial EEPROM, the bit's assertion is present before the Ports begin Link training. In that case, the Ports directly transition to the LTSSM *Loopback* state from the *LTSSM Configuration* state. The LTSSM exits the *Polling* state and enters the *Configuration.LinkWidth.Start* state, then immediately transitions to the *Master Loopback.Entry* state.

At this point, users can sample the Port's **Even/Odd Port Physical Layer Command/Status** register *Port x Ready as Loopback Master* bit (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port – Even Ports, offset 220h[19, 15, 11, 3], and Odd Ports, offset 224h[19, 15, 11, 3]), to determine whether the bit is Set, which indicates that the Master has reached the LTSSM *Loopback.Active* state. At this time, the PRBS engine can be enabled, by Setting the **Even/Odd Port User Test Pattern Delay** register *SerDes x PRBS Enable* bit (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port – Even Ports, offset 258h[27:24], and Odd Ports, offset 25Ch[27:24]) associated with the SerDes assigned to the Port being tested.

The PRBS Receive data checker first synchronizes the de-serialized parallel data words from the returned pattern with a reference PRBS pattern generator. At this point, users should check the Lane synchronization status in the **Even/Odd Port Loopback Master Status/Control** register *PRBS Pattern Sync Status Device Lane x* bits (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port – Even Ports, offset B80h[19:16], and Odd Ports, offset B84h[19:16]). If there is no synchronization, there is likely a physical connection problem. Once synchronized, the PRBS checker looks for errors, on a continuous basis. Any errors detected are logged in one or more of the **Even/Odd Port SerDes Quad x Diagnostic Data** register RO bits (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offsets 240h and 244h, bits [30 and 23:0]). The errors can be retrieved, by reading the appropriate bit.

If the *Port x Loopback Command* bits are not Set through the serial EEPROM, the Ports' Loopback Training Sets can be used to cause the Ports to linkup, by way of a Configuration cross-link track, resulting with the Ports being in L0 Link PM state. This linkup of a Port, in response to its own Training Sets, only works if the Port's **Even/Odd Port Loopback Master Status/Control** register *Port x External Loopback Enable* bit (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port – Even Ports, offset B80h[12:10, 8], and Odd Ports, offset B84h[12:10, 8]) is Set by serial EEPROM. Once the Port is in the L0 Link PM state, Configuration Space register programming can then be performed manually, to invoke a Master Loopback operation.

Once the Ports linkup, users can direct the Ports into an Analog Loopback Master condition, by writing the *Port x Loopback Command* bit(s), through the upstream Port and/or I<sup>2</sup>C Slave interface. However, this is not sufficient to initiate the LTSSM transition from the L0 Link PM state, to the *Loopback* state. The Link must pass through a *Recovery* substate, before the *Port x Loopback Command* bits can be sampled and allow the LTSSM to pass through the *Recovery* state to the *Loopback* state. To cause the Port to enter the *Recovery* state, users must Set the Port's **Link Control** register *Retrain Link* bit (offset 78h[5]). At this point, users should monitor the Port's *Port x Ready as Loopback Master* bit(s), and when Set, the PRBS engine(s) can be enabled, as previously described.

If loopback cables are attached after the device powers up, then those Ports whose Lanes are floating unconnected did not detect Receivers. Therefore, those Ports are not trained up to the L0 Link PM state.

If the Port's *Port x Loopback Command* and *Port x External Loopback Enable* bit(s) for the downstream Ports to be tested are written **before** the cables are attached, then once cabled, there is Receiver detection, the Port(s) go through Link training, and then exit the *LTSSM Configuration* state and directly enter the *Loopback* state.

However, if the Port's *Port x Loopback Command* and *Port x External Loopback Enable* bit(s) are Set **after** the cables are attached, the Ports do not recognize their own Training Sets and will likely cycle back and forth between *Configuration* and *Detect*. Therefore, users must at least Set the *Port x External Loopback Enable* bit for the Ports being tested, by way of serial EEPROM, if the PEX 8609 is powered up before the cables are attached. Users can then program the Port's *Port x Loopback Command* bit(s). In addition to this, a forced retrain is also needed, to enter into the *Loopback* state through the *Recovery* state, as previously described.

## 20.2.3 Digital Loopback Master Mode

The only difference between Analog and Digital Loopback Master modes is that the external device is assumed to have at least an Elastic buffer in the Loopback data path. Because of this, SKIP Ordered-Sets must be included in the test data pattern, which precludes use of the PRBS engine.

Figure 20-3 illustrates a Far-End Digital Loopback Master connection and data path.

The PEX 8609 provides a User Test Pattern engine on a per-Lane basis, for Digital Far-End Loopback testing. The user pattern itself, however, is common to all Lanes where it is enabled. Details on the use of the User Test Pattern registers and controls are described later in Section 20.5.

What is important to note about the data path (not shown in Figure 20-3) is that the pattern generators and checkers in the PEX 8609 Digital Loopback Master have 8/10b encode, 10b/8b decode, and Elastic buffers included in the Tx/Rx path. The scramblers and de-scramblers are disabled. Therefore, the Digital Loopback Slave device must not scramble the returning data. The 10-bit data can be decoded to 8-bit, and encoded back to 10-bit as an option, and will not affect the UTP pattern checker in the PEX 8609, unless there is a coding error.

Digital Loopback Master mode is established by either programming method previously described in Section 20.2.2 for Analog Loopback Master mode. The Port's **Even/Odd Port Physical Layer Command/Status** register *Port x Loopback Command* bit (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port – Even Ports, offset 220h[16, 12, 8, 0], and Odd Ports, offset 224h[16, 12, 8, 0]) can be Set with a serial EEPROM, causing Loopback to be entered directly from the LTSSM *Configuration* state. Otherwise, the Port's *Port x Loopback Command* bit can be Set after linkup, and then the Port's **Link Control** register *Retrain Link* bit (offset 78h[5]) can be used to move the Port to the *Loopback* state, through the LTSSM *Recovery* state.

Once Digital Loopback Master mode is established, Configuration Space register Writes are used to establish a User Test Pattern transmission, as well as error checking, which are described later in Section 20.3.

The UTP is multiplexed, unconditionally, onto the Transmit data path, upon Setting one or more of the **Even/Odd Port User Test Pattern Delay** register *SerDes x User Test Pattern Enable* bits (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port – Even Ports, offset 258h[19:16], and Odd Ports, offset 25Ch[19:16]).

**Note:** It is important to verify that the LTSSM is in a Master Loopback.Active state, before writing 1 to the *SerDes x User Test Pattern Enable* bits. Therefore, do not use the serial EEPROM to Set the *SerDes x User Test Pattern Enable* bits. (Refer to Section 20.4 for details.)

Figure 20-3. Digital Far-End Loopback

## 20.2.4 Analog Loopback Slave Mode

The PEX 8609 becomes an Analog Loopback Slave (as illustrated in Figure 20-4) if it receives Training Sets with the *Loopback* Training Control Bit Set while the **Common Physical Layer Safety and Test** register *Analog Loopback Enable* bit (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offset 23Ch[21]) is Set. It is recommended that the *Analog Loopback Enable* bit be Set first, before bringing the PEX 8609 into an LTSSM Slave *Loopback.Active* state.

As previously described, Analog Loopback does not have only pure analog circuitry in the Slave's data path. While in this mode, the received data and recovered clock are looped back from the SerDes Parallel Receive Data interface to the Parallel Transmit interface. Internal to the SerDes, the serial-to-parallel and parallel-to-serial converters are included in the Loopback data path. The re-serialized data is transmitted back to the Master device, synchronous to that Master's Reference Clock.

The multiplexing control that enables Parallel data from the Receive path, directly back to the Transmit path, is held off from asserting until the Slave reaches the *Loopback.Active* state. Then, the Parallel Recovered data and clock are multiplexed back into the SerDes Parallel Transmit interface. That multiplexer remains effective until the PEX 8609 Loopback Slave exits the *Loopback.Active* state. There are alternate ways to transition out of the Slave *Loopback.Active* state:

- If the Loopback is operating at Gen 2 (5.0 GT/s) Link speed, receipt of four consecutive Electrical Idle Ordered-Sets (EIOS) causes a Loopback exit
- If the Link is operating at Gen 1 (2.5 GT/s) Link speed, then receipt of a single EIOS, or detection of Electrical Idle entry, causes an exit
- If the Slave device appears to be “stuck” in the *Loopback.Active* state, toggling of the Port's **Even/Odd Port Physical Layer Command/Status** register *Port x Loopback Command* bit (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port – Even Ports, offset 220h[16, 12, 8, 0], and Odd Ports, offset 224h[16, 12, 8, 0]), from 0 to 1 to 0, breaks the LTSSM out of Loopback Slave operation

Figure 20-4. Analog Loopback Slave Mode

Analog Loopback Slave mode is most suitable for a PRBS test pattern. However, because the PEX 8609 includes only the SerDes in the Loopback data path, and the Transmit data is clocked out at the recovered clock frequency, the Master can include SKIP Ordered-Sets in its data pattern, regardless of whether the system uses synchronous or asynchronous clocking, as long as it can tolerate the presence of SKIP Ordered-Sets in the data pattern. In this case, the Master sees its own SKIP Ordered-Sets returned to it, at the same intervals and positions in the data pattern.

If the Master device is not capable of bringing the PEX 8609 to a Slave *Loopback.Active* state (such as a Bit Error Rate Tester (BERT) as the Master) through the LTSSM state transition arcs previously described, there is a way to unconditionally force the Slave into Analog Loopback Slave mode, through device Configuration Space register Writes to the appropriate bit states. The *BERT Loopback Path Enable* bits (**Even/Odd Port Physical Layer Test** register *Lane x Parallel Loopback Path Enable* bits (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port – Even Ports, offset 228h[28:26, 24], and Odd Ports, offset 22Ch[28:26, 24])) are first Set for all device Lanes associated with the Port being tested.

Next, the **Common Physical Layer Safety and Test** register *Analog Loopback Enable* bit (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offset 23Ch[21]) is Set. The Lanes enabled by the BERT's *Lane x Parallel Loopback Path Enable* bits immediately go into an Analog Loopback path mode, *regardless of the Slave's current LTSSM state*.

Concurrently Setting the *Analog Loopback Enable* and BERT's *Lane x Parallel Loopback Path Enable* bits, for all Lanes of the Port being tested, changes the Loopback data path, as described; however, that does not guarantee that the SerDes Transmitters are powered on and operating at the correct speed. Other PHY Safety bits can be used to ensure that the SerDes are powered up and ready to be placed into Analog Loopback Slave mode. The **Even/Odd Port Disable/Quiet/Test Pattern Rate** register (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offsets 230h and 234h) contains useful bits for controlling loopback operations:

- *Disable Port x* bits – Even Ports, offset 230h[4:2, 0], and Odd Ports, offset 234h[4:2, 0]
- *Hold Port x Quiet* bits – Even Ports, offset 230h[12:10, 8], and Odd Ports, offset 234h[12:10, 8]
- *Port x Test Pattern x Rate* bits – Even Ports, offset 230h[20:18, 16], and Odd Ports, offset 234h[20:18, 16]

The Port's *Hold Port x Quiet* bit holds the Port in the *Detect.Quiet* state once it enters that state, and does not allow the LTSSM to advance. The Port's *Hold Port x Quiet* bits also keep the SerDes Transmitters and Receivers powered on, as long as the Port's *Disable Port x* bit is not Set. The Port's *Port x Test Pattern x Rate* bit, if Set, forces the Port's SerDes to shift their Link speed to Gen 2 (5.0 GT/s) if the Port's *Hold Port x Quiet* bit is also Set.

When forcing the PEX 8609 into Analog Loopback Slave mode with a BERT attached, the Port's LTSSM looks at whatever the BERT is transmitting on the attached Lanes. Because the BERT does not transmit Training Sets, the LTSSM detects Receivers, goes to the *Polling* state, times out, and then returns to the *Detect* state to try again. The LTSSM should remain in the *Detect.Quiet* state once it returns to that state. The Port's *Hold Port x Quiet* bit, therefore, should be Set, to hold the PEX 8609 in a stable LTSSM *Detect.Quiet* state, that keeps the SerDes powered on and prevents additional state transitions. If it is necessary for the BERT to test the SerDes at the Gen 2 rate, Set the Port's *Port x Test Pattern x Rate* bit before Setting its *Hold Port x Quiet* bit.

*To Set the necessary bits prior to BERT testing, for the Port being tested:*

1. Use I<sup>2</sup>C to Set the Port's **Even/Odd Port Quiet** register *Hold Port x Quiet* bit (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port – Even Ports, offset 230h[12:10, 8], and Odd Ports, offset 234h[12:10, 8]).
2. If Analog Loopback Slave mode must operate at the Gen 2 rate (5.0 GT/s), Set the Port's **Even/Odd Port Test Pattern Rate** register *Port x Test Pattern x Rate* bit (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port – Even Ports, offset 230h[20:18, 16], and Odd Ports, offset 234h[20:18, 16]).
3. Set the BERT's **Even/Odd Port Physical Layer Test** register *Lane x Parallel Loopback Path Enable* bit(s) (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port – Even Ports, offset 228h[28:26, 24], and Odd Ports, offset 22Ch[28:26, 24]).
4. Set the **Common Physical Layer Safety and Test** register *Analog Loopback Enable* bit (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offset 23Ch[21]).

The Slave device should now be in Analog Loopback Slave, properly powered, and at the correct Link speed for BERT testing.

## 20.2.5 Digital Loopback Slave Mode

When a PEX 8609 Port is in the LTSSM Slave *Loopback.Active* state, it automatically becomes a Digital Loopback Slave, by default. The Port enters this state after it receives Training Sets with the *Loopback* Training Control Bit Set.

When a PEX 8609 Port is a Digital Loopback Slave, it includes the Elastic buffer, 8b/10b decoder, and 8b/10b encoder in the Loopback data path. The Loopback Master must provide the test data pattern and data pattern checker (such as a PEX 8609 User Test Pattern). The Loopback Master must also transmit SKIP Ordered-Sets with the data pattern. Depending upon the PEX 8609 Reference Clock source's PPM offset, the PEX 8609 Digital Loopback Slave's Elastic buffers can compensate for the offset, by returning more or fewer SKIP symbols than the PEX 8609 received from the Master. Therefore, the Master's data pattern checker must make provisions for this when decoding for errors.

This mode is **not** suitable for a PRBS pattern as transmitted from the Master, because neither device can compensate for Reference Clock offset differences, should they exist.

Unlike Analog Loopback Slave mode (described in [Section 20.2.4](#)), there is no way to unconditionally force the Loopback path into Digital Loopback Slave mode, through the use of PHY-related register bits – the Slave must be brought into the mode by a Master-connected device, through standard LTSSM tracks.

**Figure 20-5. Digital Loopback Slave Mode**

## 20.3 User Test Pattern

The PEX 8609 provides a User Test Pattern (UTP) Transmit and Receive data checker, for Digital Far-End Loopback testing. (Refer to [Figure 20-3.](#)) After LTSSM Loopback Master mode is established, Configuration Writes are used to fill the **Physical Layer User Test Pattern, Bytes x through y** registers (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offsets [210h](#) through [21Ch](#)). One or more **Even/Odd Port User Test Pattern Delay** register *SerDes x User Test Pattern Enable* bits (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port – Even Ports, offset [258h](#)[19:16], and Odd Ports, offset [25Ch](#)[19:16]) are used to start the UTP transmission, on the Lanes assigned to each bit. The UTP logic assumes that there is asynchronous clocking between the PEX 8609 Loopback Master and the connected Slave device. Therefore, the expectation is that there is at least a clock-crossing boundary in the Slave device's Loopback data path (*such as* an Elastic buffer). SKIP Ordered-Sets are inserted into the user's test data pattern, at the nearest data pattern boundary according to the programmed SKIP interval. That interval is determined by the **Common Physical Layer Safety and Test** register *SKIP Ordered-Set Interval* field (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offset [23Ch](#)[19:8]) value. The default interval is 1,180 symbol times.

The Test Pattern checker ignores SKIP Ordered-Sets returned by the Loopback Slave, because the quantity of SKIP symbols received can be different from the quantity transmitted. All other data is compared to the transmitted data, and errors are logged in the **Even/Odd Port SerDes Quad x Diagnostic Data** registers (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offsets [240h](#) and [244h](#)).

The 16-byte UTP is loaded into the **Physical Layer User Test Pattern, Bytes x through y** registers. The pattern is common to all Lanes. Prior to transmission, the 8b/10b encoder converts the 16 bytes to 10-bit encoded data. Pattern bytes only go out as control symbols (k-bit set), if the Lane's **Common Physical Layer Command/Status** register *User Test Pattern K-Code Flag* bit (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offset [238h](#)[31:16]) is Set.

**Caution:** *Use caution when Setting User Test Pattern K-Code Flag bits, because UTP logic does not check the validity of Control characters.*

The UTP Transmitter logic does not immediately transmit the UTP bytes upon being enabled – a fixed, 4-byte sync pattern ([5243h](#)) is continuously transmitted first. The sync word detection validates the physical Loopback wiring and connected device Loopback path, to qualify the UTP transmission's initiation. The sync DWord allows the Pattern Checking logic to determine the starting boundary of the received pattern byte sequence. Sync detection also enables Received Data error checking and logging. Unfortunately, there are no sync-acquired status bits in the Physical Layer registers, like there are for PRBS; therefore, it is not possible to verify that the sync pattern has been detected. However, a single UTP Error Count is logged if the sync pattern is not detected within 256 ns from the initial transmission of the sync DWord. Therefore, a single Error Count may, or may not, indicate the absence of received sync data (*for example*, a good sync could have been followed by a single bit error).

**Notes:** *There are no explicit Control bits for deliberately injecting UTP errors into the transmission, to test the error checking ability. However, one way of testing the ability is to write a test pattern byte to a different value after the transmission has started. That usually causes a temporary unequal boundary condition, which will log an error. While not guaranteed to inject an error, this method is useful for testing error checking ability.*

*A UTP is not recommended for Master mode far-end cable testing, especially when initiated by way of serial EEPROM from a power-up sequence. If a UTP is enabled and looped back before Link training begins, the symbol framers will not have seen any COM symbols, and the true 10-bit symbol boundaries are unknown. The framer requires three COMs in a row, in the same bit position, to achieve symbol lock. Neither the sync pattern, nor the user pattern, would be detected in this case, and the test is certain to fail.*

In addition to the 16-byte pattern registers, the UTP is enabled on a per-Lane basis, by Setting the **Even/Odd Port User Test Pattern Delay** register *SerDes x User Test Pattern Enable* bit (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port – Even Ports, offset [258h](#)[19:16], and Odd Ports, offset [25Ch](#)[19:16]), for the SerDes associated with the Port being tested.

**Note:** *The UTP is unconditionally multiplexed onto the Transmit data path, upon Setting the SerDes x User Test Pattern Enable bits. Therefore, it is necessary to verify that the LTSSM is in an LTSSM Master Loopback.Active state **before** writing a value of 1 to those Enable bits. **Do not use a serial EEPROM to Set the SerDes x User Test Pattern Enable bits.***

UTP testing results can be monitored in one of the **Even/Odd Port SerDes Quad x Diagnostic Data** registers (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offsets [240h](#) and [244h](#)). Each register can be used to examine the Error Count in the [UTP/PRBS Error Counter](#) field [[23:16](#)], and expected/actual data of the first failing byte (fields [[7:0](#) and [15:8](#)], respectively). The *Status* bits are on a per-Lane basis associated with a SerDes quad. **The important field in these registers is the [SerDes Diagnostic Data Select](#) field [[25:24](#)].** When the Lane code for the quad is written to that field, the UTP status for that Lane appears in the *Status* fields. Bit [30](#) of the register ([PRBS Counter/-UTP Counter](#)) is a pattern type indicator, and is Cleared when UTP is enabled for a Lane.

**Notes:** *Use of the Diagnostic registers is explained in [Section 20.5](#).*

***The UTP and PRBS Enables are mutually exclusive, and must not be Set concurrently. If both Enables are simultaneously Set, the resulting operation is undefined. The UTP/PRBS Error Counter field continues to count, until it saturates at 255. To clear the Counter and allow it to begin logging errors again, write all zeros (0) to that field. Alternatively, the Counter status is Cleared if the SerDes x User Test Pattern Enable bit for that Lane is Cleared, and then Set again.***

## 20.4 Pseudo-Random Bit Sequence

A Pseudo-Random Bit Sequence (PRBS) generator and checker are useful as a diagnostic/debugging tool, and for measuring short- or long-term bit error rates in PCI Express systems. The PEX 8609 also uses a specially enabled power-up self-test that runs after reset, as a wafer sort test for use on automated test equipment. PRBS pattern generators and checkers reside within the SerDes\_rclk\_blk modules, because they transmit and receive 10- or 20-bit data directly to/from the SerDes quads. Locating them in the modules helps ensure tight timing and short trace length on SerDes Tx and Rx parallel data.

The PEX 8609 PRBS logic is enabled by one or more of the **Even/Odd Port User Test Pattern Delay** register *SerDes x PRBS Enable* bits (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port – Even Ports, offset 258h[27:24], and Odd Ports, offset 25Ch[27:24]), for the SerDes associated with the Port being tested. Prior to enabling PRBS, an externally connected PCI Express device must be in an LTSSM Slave *Loopback.Active* state. Furthermore, the reference clocking between the two devices must be synchronous. (*That is, the returning PRBS pattern must have its transmission clock source synchronous to the PEX 8609 Reference Clock.*) The PEX 8609 PRBS pattern generator does not insert any SKIP Ordered-Sets, and, if the Slave device inserts SKIP Ordered-Sets into the returning pattern, they cannot be ignored by the PRBS checker (it causes an error). Alternatively, the PRBS pattern can be used to test an external cable Loopback, after the correct LTSSM Master *Loopback.Active* state is reached, as described in [Section 20.2.2](#).

After a PEX 8609 Lane's PRBS engine is enabled, the PRBS engine immediately begins to transmit the PRBS pattern on that Lane. No 8b/10b encoding is performed. The PRBS pattern generator produces 10- or 20-bit symbols on every Clock cycle, depending upon the current Link speed. The symbols are written directly into the SerDes Tx data Port, for immediate transmission.

The PRBS Receive Data Checking logic first synchronizes the de-serialized 10- or 20-bit Parallel Data symbols from the SerDes Rx data Port, using a reference PRBS pattern generator. After pattern synchronization is achieved, the Receive data checker begins comparing the Rx data symbols on a continuous basis, to discover any mismatch between a symbol's expected and received values.

**Note:** *Error checking cannot begin until synchronization is achieved; therefore, it is important to monitor the pattern synchronization status, before checking the error status. Synchronization status is available in the **Even/Odd Port Loopback Master Status/Control** register PRBS Pattern Sync Status Device Lane x bits (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port – Even Ports, offset B80h[19:16], and Odd Ports, offset B84h[19:16]). **This status should always be checked.** If there is no synchronization, there is likely a physical connection problem. Any errors detected are logged in one or more of the **Even/Odd Port SerDes Quad x Diagnostic Data** registers (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offsets 240h and 244h). Use of these registers is explained in [Section 20.5](#).*

It is possible to inject errors into a PRBS pattern while it is transmitting on a per-Lane basis, for testing the ability to find and count errors, by programming the **Even/Odd Port SerDes Quad x Diagnostic Data** register *PRBS Error Injection* field(s) (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offsets [240h](#) and [244h](#), field [29:26]) to 1h. When enabled, an error is injected, by corrupting a single bit in one PRBS pattern symbol once every 127 words.

PRBS testing results can be monitored in one of the **Even/Odd Port SerDes Quad x Diagnostic Data** registers (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offsets [240h](#) and [244h](#)). Each register can be used to examine the Error Count in the *UTP/PRBS Error Counter* field [23:16], and expected/actual data of the first failing byte (fields [7:0 and 15:8], respectively). The *Status* bits are on a per-Lane basis associated with a SerDes quad. **The important field in these registers is the *SerDes Diagnostic Data Select* field [25:24].** When the Lane code for the quad is written to that field, the PRBS status for that Lane appears in the *Status* fields. Bit 30 of the register (*PRBS Counter/-UTP Counter*) is a pattern type indicator, and is Set when PRBS is enabled for a Lane.

**Notes:** Use of the Diagnostic registers is explained in [Section 20.5](#).

***The UTP and PRBS Enables are mutually exclusive, and must not be Set concurrently.***

*If both Enables are simultaneously Set, the resulting operation is undefined. The UTP/PRBS Error Counter field continues to count, until it saturates at 255. To Clear the Counter and allow it to begin logging errors again, write all zeros (0) to that field. Alternatively, the Counter status is Cleared if the SerDes x User Test Pattern Enable bit for that Lane is Cleared, and then Set again.*

*The PRBS Error Count does not necessarily represent a true Bit Error rate. The PRBS checker detects one or more mismatched bits in each examined symbol, on a symbol-per-core-clock basis. Therefore, the Error Counter advances one count for every symbol mismatch, regardless of how many bits are in error for that failing symbol.*

## 20.4.1 Physical Layer Built-In Self-Test

The PEX 8609 also uses the PRBS engines in a special power-up self-test of all SerDes. This is called *Physical Layer Built-In Self-Test (PHY BIST)*, and is intended for production wafer sorting, to screen out die that have basic SerDes Rx/Tx data/clock circuitry faults. The test uses the Internal Serial Loopback mode, whereby the serial Tx data is looped back to the serial Rx data path prior to the differential pad buffer cells. PHY BIST is enabled with a unique code (5h; LHLH) applied to the [STRAP\\_TESTMODE\[3:0\]](#) device Ports, and runs at Gen 2 (5.0 GT/s) Link speed.

**Note:** *If the SerDes must be brought up to 5.0 GT/s, it must be done without bringing the Link up in the same way that the Functional logic would bring the SerDes up. Instead, the PHY BIST uses the PIPE interface Rate signaling sequence, to change the speed before it starts up the PRBS generators, and then checks for Sync and Data errors.*

After the PHY Reset is released, the PHY BIST logic starts up if PHY BIST is enabled. If enabled, Internal Serial Loopback mode, as well as the PRBS engines for all device Lanes, are also enabled. PRBS Loopback pattern generation runs for 16 ms, and then stops. Any errors detected are logged in a special status, that is enabled onto the GPIO[5, 3:0] balls. [Table 20-2](#) lists the GPIO[5, 3:0] mappings of the PHY BIST Status signals, for automated test equipment sensing and debug.

**Table 20-2. PHY BIST Status at Device Ports**

| Device Ball Name | PHY BIST Status                     |
|------------------|-------------------------------------|
| GPIO0            | PHY BIST Error Status               |
| GPIO1            | PHY BIST Done Status                |
| GPIO2            | PHY BIST All Sync OK Status         |
| GPIO3            | PHY SerDes Quad 0 BIST Error Status |
| GPIO5            | PHY SerDes Quad 2 BIST Error Status |

## 20.5 Using the Even/Odd Port SerDes Quad x Diagnostic Data Registers

Each SerDes quad has its own Diagnostic Data register. The **Even/Odd Port SerDes Quad x Diagnostic Data** register (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offsets [240h](#) and [244h](#)) contents reflect the performance of the SerDes selected by the registers' *SerDes Diagnostic Data Select* field [25:24], as defined in [Table 20-3](#). This control is specific to this register (which reports results of UTP and PRBS tests).

When field [25:24] is Cleared, the information in that Diagnostic Data register is for the first SerDes within that SerDes quad. When field [25:24] is programmed to 01b, the information in that Diagnostic Data register is for the second SerDes within that SerDes quad. Following this pattern, a value of 10b indicates the third SerDes within that SerDes quad, and a value of 11b indicates the fourth SerDes within that SerDes quad.

**Table 20-3. Even/Odd Port SerDes Quad x Diagnostic Data Register Contents**  
(Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offsets 240h and 244h)

| Register Offset      | Register                                          | SerDes Diagnostic Data Select Field [25:24] Value |          |          |          |
|----------------------|---------------------------------------------------|---------------------------------------------------|----------|----------|----------|
|                      |                                                   | 00b                                               | 01b      | 10b      | 11b      |
| <a href="#">240h</a> | <b>Even Ports – SerDes Quad 0 Diagnostic Data</b> | SerDes 0                                          | SerDes 1 | SerDes 2 | SerDes 3 |
| <a href="#">244h</a> | <b>Odd Ports – SerDes Quad 2 Diagnostic Data</b>  | SerDes 4                                          | SerDes 5 | SerDes 6 | SerDes 7 |

## 20.6 Pseudo-Random and Bit-Pattern Generation

Each SerDes quad has an associated PRBS generator and checker. The PRBS generator is based upon a 7-bit **Linear Feedback Shift** register (**LFSR**), which can generate up to  $(2^7 - 1)$  unique patterns. The PRBS logic is assigned to a SerDes in the quad, by manipulating the appropriate **Even/Odd Port SerDes Quad x Diagnostic Data** register *SerDes Diagnostic Data Select* bits (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offsets 240h and 244h, field [25:24]). The PRBS bit stream is used for Analog Far-End Loopback testing.

The PEX 8609 also provides a method of creating a repeating programmable bit pattern. Each of the four 32-bit **Physical Layer User Test Pattern, Bytes x through y** registers (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offsets 210h through 21Ch) are loaded with a 32-bit data pattern. After a Port is established as a Loopback Master, Set the appropriate **Even/Odd Port User Test Pattern Delay** register *SerDes x User Test Pattern Enable* bit(s) (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port – Even Ports, offset 258h[19:16], and Odd Ports, offset 25Ch[19:16]), for the SerDes associated with that Port. The PEX 8609 proceeds to transmit the data pattern on all Lanes, starting with Byte 0 of the **Physical Layer User Test Pattern, Bytes 0 through 3** register and continuing, in sequence, through Byte 3 of the **Physical Layer User Test Pattern, Bytes 12 through 15** register. SKIP Ordered-Sets are inserted at the proper intervals, which makes this method appropriate for Digital Far-End Loopback testing. The received pattern is compared to the transmitted pattern. Any errors are logged and can be retrieved, by reading the appropriate **Even/Odd Port SerDes Quad x Diagnostic Data** register RO bits (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offsets 240h and 244h, bits [30 and 23:0]).

*To produce a pseudo-clock bitstream in Analog Loopback mode, Set the registers as follows:*

1. In the Slave device, enable Analog Loopback by Setting the **Common Physical Layer Safety and Test** register *Analog Loopback Enable* bit (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offset 23Ch[21]).
2. In the PEX 8609 Loopback Master device, Set the Port's **Even/Odd Port Physical Layer Command/Status** register *Port x Loopback Command* bit (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port – Even Ports, offset 220h[16, 12, 8, 0], and Odd Ports, offset 224h[16, 12, 8, 0]).
3. Check whether loopback is successful, by reading the Port's **Even/Odd Port Physical Layer Command/Status** register *Port x Ready as Loopback Master* bit (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port – Even Ports, offset 220h[19, 15, 11, 3], and Odd Ports, offset 224h[19, 15, 11, 3]) in the same Nibble that was Set in step 2. The Nibble value is 9h if Loopback was successful.
4. Set the **Even/Odd Port User Test Pattern Delay** register *SerDes x PRBS Enable* bit (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port – Even Ports, offset 258h[27:24], and Odd Ports, offset 25Ch[27:24]) for the SerDes associated with the Port selected in step 2.
5. Check the **Even/Odd Port Loopback Master Status/Control** register *PRBS Pattern Sync Status Device Lane x* bits (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port – Even Ports, offset B80h[19:16], and Odd Ports, offset B84h[19:16]). A bit returning a value of 1 indicates that the looped-back PRBS pattern is detected at the Master's Receiver.
6. Exit Loopback mode, by Clearing the following bits:
  - a. *SerDes x PRBS Enable* bit, for the SerDes (selected in step 4) used by the Port selected in step 2.
  - b. *Port x Loopback Command* bit, for the Port selected in step 2.

Clearing these bits causes both sides of the Link to exit their LTSSM *Loopback* states, and return to the L0 Link PM state.

## 20.7 PHY Testability Features

The PEX 8609 includes several Configuration bits to ease PHY testability. Features include:

- Full support of the standard and modified compliance patterns
- Register controllability of the common block and Lane-specific inputs of the SerDes

Table 20-4 describes the Configuration bits.

**Table 20-4. Configuration Bits to Ease PHY Testability**

| Register Bit(s) <sup>a</sup>                                                                                                                                                                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>SerDes x Mask Electrical Idle Detect</i><br><br><b>Even/Odd Port Electrical Idle for Compliance Mask</b> registers<br>(Even Ports, offset 200h[11:8], and<br>Odd Ports, offset 204h[11:8])       | When any one of these bits is Set, the Electrical Idle condition flag of the corresponding Lane does not assert, regardless of the actual presence of Electrical Idle.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <i>SerDes x Mask Receiver Not Detected</i><br><br><b>Even/Odd Port Receiver Detect Mask</b> registers<br>(Even Ports, offset 200h[19:16], and<br>Odd Ports, offset 204h[19:16])                     | When any one of these bits is Set, the PHY functions as if a Receiver was detected on the corresponding Lane, regardless of the actual presence of a Receiver.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <i>Test Pattern x</i><br><br><b>Physical Layer User Test Pattern, Bytes x through y</b> registers<br>(offsets 210h through 21Ch)                                                                    | A 16-byte test pattern can be written to these four registers. When UTP transmission is enabled, Byte 0 of register offset 210h is transmitted first and Byte 3 (Byte 15 of the UTP) of register offset 21Ch is transmitted last. (Refer to <a href="#">Section 20.2.3</a> for further details.) Every byte of the UTP can be a Control or Data character. Illegal Control characters can be specified.                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <i>Port x Scrambler Disable Command</i><br><br><b>Even/Odd Port Physical Layer Command/Status</b> registers<br>(Even Ports, offset 220h[17, 13, 9, 1],<br>and Odd Ports, offset 224h[17, 13, 9, 1]) | Unconditionally disables the data scramblers on the Lanes of the corresponding Port, and causes the <i>Scrambler Disable</i> Training Control Bit to be Set in transmitted Training Sets. There is one bit for each Port.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <i>Disable Port x</i><br><br><b>Even/Odd Port Disable</b> registers<br>(Even Ports, offset 230h[4:2, 0],<br>and Odd Ports, offset 234h[4:2, 0])                                                     | When Set, LTSSM remains in the <i>Detect.Quiet</i> state on Port 0, if it is currently in, or returns to, that state. Unconditionally disables the corresponding Port. This is different from the <i>LTSSM Disabled</i> state, in that the Port does not attempt to enter this state. If the Port is idle, it ceases attempting to detect a Receiver. If the Port is up, it immediately returns to the <i>Detect.Quiet</i> state and remains there. No Electrical Idle Ordered-Set (EIOS) is sent, which could force any connected device to the <i>Recovery</i> state, and then to the LTSSM <i>Detect</i> state. The Port remains disabled until its <i>Disable Port x</i> bit is Cleared. While the Port is disabled, Receiver termination is disabled and the SerDes that belong to the disabled Port are placed into the L1 Link PM state. |
| <i>Hold Port x Quiet</i><br><br><b>Even/Odd Port Quiet</b> registers<br>(Even Ports, offset 230h[12:10, 8],<br>and Odd Ports, offset 234h[12:10, 8])                                                | When Set, the LTSSM remains in the <i>Detect.Quiet</i> state if it is currently in, or returns to, that state.<br><br>Unlike the <i>Disable Port x</i> bits, these bits do not force the LTSSM into the <i>Detect.Quiet</i> state. Once in the <i>Detect.Quiet</i> state, Receiver termination is enabled and the Transmitters are placed into the L0 Link PM state. This Port can now transmit test patterns (PRBS or UTP), with or without an attached device and without being in the <i>Loopback.Active</i> state.                                                                                                                                                                                                                                                                                                                          |

**Table 20-4. Configuration Bits to Ease PHY Testability (Cont.)**

| Register Bit(s) <sup>a</sup>                                                                                                                                                | Description                                                                                                                                                                                                                                                                           |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>Port x Test Pattern x Rate</i><br><br><b>Even/Odd Port Test Pattern Rate</b> registers<br>(Even Ports, offset 230h[20:18, 16],<br>and Odd Ports, offset 234h[20:18, 16]) | The corresponding Port transmits the selected test pattern (PRBS or UTP) at 5.0 GT/s, if the Port's <i>Hold Port x Quiet</i> bit is also Set (manual rate selection is enabled only when the <i>Hold Port x Quiet</i> bit is Set).                                                    |
| <i>Port x Receiver Error Counter</i><br><br><b>Even/Odd Port Receiver Error Counters</b> registers<br>(offsets B88h through B94h)                                           | Contains four 8-bit fields that, when read, return the quantity of Receiver errors detected by the corresponding Port. The Error Counter saturates at 255.<br><br>The Counter is Cleared with any Write to the corresponding byte in these registers; otherwise, this register is RO. |

- a. All registers listed in this table are located in Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port.

## 20.8 JTAG Interface

The PEX 8609 provides a Joint Test Action Group (JTAG) Boundary Scan interface, which is used to debug board connectivity for each ball.

### 20.8.1 *IEEE 1149.1* and *IEEE 1149.6* Test Access Port

The *IEEE Standard 1149.1* Test Access Port (TAP), commonly called the *JTAG Debug Port*, is an architectural standard described in the *IEEE Standard 1149.1-1990*. The *IEEE Standard 1149.6-2003* defines extensions to *1149.1* to support PCI Express SerDes testing. These standards describe methods for accessing internal device facilities, using a four- or five-signal interface.

The JTAG Debug Port, originally designed to support scan-based board testing, is enhanced to support the attachment of debug tools. The enhancements, which comply with the *IEEE Standard 1149.1-1994 Specifications for Vendor-Specific Extensions*, are compatible with standard JTAG hardware for boundary-scan system testing.

- **JTAG Signals** – JTAG Debug Port implements the four required JTAG signals – [JTAG\\_TCK](#), [JTAG\\_TDI](#), [JTAG\\_TDO](#), [JTAG\\_TMS](#) – and optional [JTAG\\_TRST#](#) signal
- **Clock Requirements** – JTAG\_TCK signal frequency ranges from 0 to 20 MHz
- **JTAG Reset Requirements** – Refer to [Section 20.8.4](#)

## 20.8.2 JTAG Instructions

The JTAG Debug Port provides the *IEEE Standard 1149.1-1990* BYPASS, EXTEST, SAMPLE, PRELOAD, CLAMP, and IDCODE instructions. *IEEE Standard 1149.6-2003* EXTEST\_PULSE and EXTEST\_TRAIN instructions are also supported. [Table 20-5](#) lists the JTAG instructions, along with their input codes; Instruction Length is 29 bits.

The PEX 8609 returns the JTAG IDCODE values listed in [Table 20-6](#).

**Table 20-5. JTAG Instructions**

| Instruction  | Input Code | Comments                         |
|--------------|------------|----------------------------------|
| BYPASS       | 1FFF_FFFFh | <i>IEEE Standard 1149.1-1990</i> |
| EXTEST       | 1FFF_FFE8h |                                  |
| SAMPLE       | 1FFF_FFF8h |                                  |
| PRELOAD      | 1FFF_FFF8h |                                  |
| EXTEST_PULSE | 1FF7_FFE8h | <i>IEEE Standard 1149.6-2003</i> |
| EXTEST_TRAIN | 1FD3_FFE8h |                                  |
| CLAMP        | 1FFF_FFEFh | <i>IEEE Standard 1149.1-1990</i> |
| IDCODE       | 1FFF_FFFEh |                                  |

**Table 20-6. JTAG IDCODE Values**

| Units | Version | Part Number          | PLX Manufacturer Identity | Least Significant Bit |
|-------|---------|----------------------|---------------------------|-----------------------|
| Bits  | 0000b   | 1000_0110_0000_1000b | 001_1100_1101b            | 1                     |
| Hex   | 0h      | 8608h                | 1CDh                      | 1h                    |

### 20.8.3 JTAG Boundary Scan

*Boundary Scan Description Language (BSDL)*, IEEE Standard 1149.1-1994, is a supplement to the IEEE Standard 1149.1-1990 and IEEE Standard 1149.1a-1993, *IEEE Standard Test Access Port and Boundary-Scan Architecture*. BSDL, a subset of the IEEE 1076-1993 *Standard VHSIC Hardware Description Language (VHDL)*, allows a rigorous description of testability features in components which comply with the standard. This standard is used by automated test pattern generation tools for package interconnect tests, and Electronic Design Automation (EDA) tools for synthesized Test logic and verification. BSDL supports robust extensions that can be used for internal test generation and to write software for hardware debug and diagnostics.

The primary components of BSDL include the logical Port description, physical ball map, instruction set, and **Boundary** register description.

The logical Port description assigns symbolic names to the device's signal balls. Each ball includes a logical type of *in*, *out*, *in out*, *buffer*, or *linkage* that defines the logical direction of signal flow.

The physical ball map correlates the device's logical Ports to the physical balls of a specific package. A BSDL description can include several physical ball maps, and maps are provided with a unique name.

Instruction Set statements describe the bit patterns that must be shifted into the **Instruction** register to place the device in the various test modes defined by the standard. Instruction Set statements also support descriptions of instructions that are unique to the PEX 8609.

The **Boundary** register description lists each cell or shift stage of the **Boundary** register. Each cell has a unique number – the cell numbered 0 is the closest to the [JTAG Test Data Output \(JTAG\\_TDO\)](#), and the cell with the highest number is closest to the [JTAG Test Data Input \(JTAG\\_TDI\)](#). Each cell includes additional information, *such as*:

- Cell type
- Logical Port associated with the cell
- Logical function of the cell
- Safe value
- Control cell number
- Disable value
- Result value

**Note:** The PEX 8609 requires Fundamental Reset ([PEX\\_PERST#](#) input assertion and de-assertion) and active REFCLK to initialize the switch, prior to using the JTAG interface.

### 20.8.4 JTAG Reset Input – JTAG\_TRST#

The [JTAG\\_TRST#](#) input is the asynchronous reset input to the JTAG TAP Controller logic. JTAG\_TRST# assertion places the PEX 8609's TAP Controller into the *Test-Logic-Reset* state, which selects the PEX 8609 standard logic path (core-to-I/O), as required for typical functionality of the switch. JTAG\_TRST# de-assertion enables the TAP Controller for test and debug functionality, such as boundary scan.

- If JTAG functionality is required, the JTAG\_TRST# input should be transitioned from Low-to-High once during PEX 8609 power-up, along with [PEX\\_PERST#](#) de-assertion. In any JTAG state, the JTAG TAP Controller can be returned to the *Test-Logic-Reset* (initial) state, by holding the [JTAG\\_TMS](#) input High while clocking the [JTAG\\_TCK](#) input at least five times.
- If the PEX 8609's JTAG TAP Controller is not intended to be used by the design, an external pull-down resistor is recommended on the JTAG\_TRST# input, because its internal pull-down resistor is weak.

## 20.9 Lane Good Status LEDs

The PEX 8609 provides Lane Good outputs, **PEX\_LANE\_GOOD[7:0]#**, that can directly drive external common anode LED modules, to provide visual indication that the PHY of that Lane's Link is trained to at least x1 width.

Software can determine:

- Which Lanes have completed PHY linkup, by performing a Memory Read of the **Software Lane Status** register *Lane x Up Status* bits (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offset **1F4h**[7:0], which correspond to Lanes [7-0], respectively).
- Whether the Link for each Port has trained, by reading either the Port's **Link Status** register *Data Link Layer Link Active* bit (offset **78h**[29]), or Port's **VC0 Resource Status** register *VC0 Negotiation Pending* and **VC1 Resource Status** register *VC1 Negotiation Pending* bits (offsets **160h**[17] and **16Ch**[17], respectively). If the *Data Link Layer Link Active* bit is Set, or *VC0 Negotiation Pending* and/or *VC1 Negotiation Pending* bit is Cleared, the Link has completed Flow Control (FC) initialization.

The **Link Status** register can be read by either a PCI Express Configuration Request or Memory Read. The **VC0 Resource Status** and **VC1 Resource Status** registers can be read by either a PCI Express Enhanced Configuration access or Memory Read.

- The negotiated Link width of each Port, by reading the Port's **Link Status** register *Negotiated Link Width* field (offset **78h**[25:20]). This register can be read by either a Configuration Request or Memory Read.

Table 20-7 describes the relationship of the LED On/Off patterns, as they relate to the Lane status indicated by **PEX\_LANE\_GOOD[7:0]#**.

**Table 20-7. PEX\_LANE\_GOOD[7:0]# LED On/Off Patterns, by State**

| State                                           | LED Pattern                               |
|-------------------------------------------------|-------------------------------------------|
| Lane is disabled                                | Off                                       |
| Lane is enabled, 5.0 GT/s                       | On                                        |
| Lane is enabled, 2.5 GT/s, reduced Lanes are up | Blinking, 0.5 seconds On, 0.5 seconds Off |

THIS PAGE INTENTIONALLY LEFT BLANK.

## Chapter 21 Electrical Specifications

### 21.1 Introduction

This chapter provides the PEX 8609 electrical specifications.

### 21.2 Power-Up/Power-Down Sequence

The PEX 8609 does not have power sequencing requirements. The power rails can be powered up and powered down, in any sequence.

### 21.3 Absolute Maximum Ratings

**Warning:** *Maximum limits indicate the temperatures and voltages above which permanent damage can occur. Proper operation at these conditions is not guaranteed, and continuous operation of the PEX 8609 at these limits is not recommended.*

**Table 21-1. Absolute Maximum Rating (All Voltages Referenced to VSS System Ground)**

| Item                                        | Symbol    | Absolute Maximum Rating | Units |
|---------------------------------------------|-----------|-------------------------|-------|
| I/O Interface Supply Voltage                | VDD25     | -0.5 to +3.6            | V     |
| PLL Supply Voltage                          | VDD25A    | -0.5 to +3.6            | V     |
| Core (Logic) Supply Voltage                 | VDD10     | -0.3 to +1.5            | V     |
| SerDes Analog Supply Voltage                | VDD10A    | -0.3 to +1.5            | V     |
| Input Voltage (2.5V Interface)              | $V_I$     | -0.3 to +3.6            | V     |
| Operating Ambient Temperature<br>Commercial | $T_A$     | 0 to +70                | °C    |
| Industrial                                  |           | -40 to +85              | °C    |
| Storage Temperature                         | $T_{STG}$ | -65 to +150             | °C    |

## 21.4 Power Characteristics

**Table 21-2. Operating Condition Power Supply Rails**

| Symbol | Parameter                                       | Min  | Typ  | Max  | Units |
|--------|-------------------------------------------------|------|------|------|-------|
| VDD10  | Digital Core Supply {1.0V $\pm$ 5%}             | 0.95 | 1.0  | 1.05 | V     |
| VDD10A | Analog SerDes Supply {1.0V $\pm$ 5%}            | 0.95 | 1.0  | 1.05 | V     |
| VDD25  | I/O Supply {2.5V $\pm$ 10%}                     | 2.25 | 2.50 | 2.75 | V     |
| VDD25A | Phase-Locked Loop (PLL) Supply {2.5V $\pm$ 10%} | 2.25 | 2.50 | 2.75 | V     |

## 21.5 Power Consumption Estimates

Table 21-3 and Table 21-4 list the PEX 8609 power consumption estimates at Gen 1 and Gen 2 Link speeds, respectively.

**Table 21-3. PEX 8609 Gen 1 (2.5 GT/s) Power Consumption Estimates (Watts)**

| Lanes | Ports | Core Digital (VDD10) (Amps) |      | SerDes Analog (VDD10A) (Amps) |      | SerDes Digital (VDD10) (Amps) |      | PLL and I/O (VDD25A/VDD25) (Amps) |      | Total (Watts)    |                     |
|-------|-------|-----------------------------|------|-------------------------------|------|-------------------------------|------|-----------------------------------|------|------------------|---------------------|
|       |       | Typ                         | Max  | Typ                           | Max  | Typ                           | Max  | Typ                               | Max  | Typ <sup>a</sup> | Max <sup>b, c</sup> |
| 8     | 8     | 0.99                        | 1.86 | 0.24                          | 0.43 | 0.05                          | 0.11 | 0.02                              | 0.03 | 1.35             | 2.59                |

- a. Typical power based upon 35% traffic, all Lanes in active L0 Link PM state, typical power rails (1.0V/2.5V).
- b. Maximum power based upon 85% traffic, idle Lanes in active L0s Link PM state, maximum power rails (1.05V/2.75V).
- c. Maximum power is at high temperature and Fast/Fast (FF) process corner silicon.

**Table 21-4. PEX 8609 Gen 2 (5.0 GT/s) Power Consumption Estimates (Watts)**

| Lanes | Ports | Core Digital (VDD10) (Amps) |      | SerDes Analog (VDD10A) (Amps) |      | SerDes Digital (VDD10) (Amps) |      | PLL and I/O (VDD25A/VDD25) (Amps) |      | Total (Watts)    |                     |
|-------|-------|-----------------------------|------|-------------------------------|------|-------------------------------|------|-----------------------------------|------|------------------|---------------------|
|       |       | Typ                         | Max  | Typ                           | Max  | Typ                           | Max  | Typ                               | Max  | Typ <sup>a</sup> | Max <sup>b, c</sup> |
| 8     | 8     | 1.21                        | 2.12 | 0.27                          | 0.51 | 0.06                          | 0.13 | 0.02                              | 0.03 | 1.60             | 2.96                |

- a. Typical power based upon 35% traffic, all Lanes in active L0 Link PM state, typical power rails (1.0V/2.5V).
- b. Maximum power based upon 85% traffic, idle Lanes in active L0s Link PM state, maximum power rails (1.05V/2.75V).
- c. Maximum power is at high temperature and Fast/Fast (FF) process corner silicon.

## 21.6 I/O Interface Signal Groupings

**Table 21-5. Signal Group PCI Express Analog Interface**

| Signal Group | Signal Type                          | Signals                                                       | Notes                                                               |
|--------------|--------------------------------------|---------------------------------------------------------------|---------------------------------------------------------------------|
| (a)          | PCI Express Output (Transmit)        | PEX_PETn[7:0],<br>PEX_PETp[7:0]                               | Refer to <a href="#">Table 21-7</a> and <a href="#">Table 21-8</a>  |
| (b)          | PCI Express Input (Receive)          | PEX_PERn[7:0],<br>PEX_PERp[7:0]                               | Refer to <a href="#">Table 21-7</a> and <a href="#">Table 21-9</a>  |
| (c)          | PCI Express Differential Clock Input | PEX_REFCLKn, PEX_REFCLKp,<br>PEX_REFCLK_CFCn, PEX_REFCLK_CFCp | Refer to <a href="#">Table 21-7</a> and <a href="#">Table 21-10</a> |
| (d)          | SerDes External Resistor             | REXT_A[1:0], REXT_B[1:0]                                      | 1.43K $\Omega$ $\pm$ 1%,<br>and refer to <a href="#">Table 21-7</a> |

**Table 21-6. Signal Group Digital Interface**

| Signal Group | Signal Type                                               | Signals                                                                                                                                                                                                                                                                                                                                                       | Note                                |

| $V_{TX-RCV-DETECT}$              | Amount of Voltage Change Allowed during Receiver Detection                                         | 600 (max)              | 600 (max)              | mV    | Total amount of voltage change that a Transmitter can apply, to sense whether a low-impedance Receiver is present.                                                                                                                                                                           |
| $T_{TX-IDLE-MIN}$                | Minimum Time Spent in Electrical Idle                                                              | 20 (min)               | 20 (min)               | ns    | Minimum time a Transmitter must be in Electrical Idle. Used by the Receiver to start looking for an Electrical Idle Exit after successfully receiving an Electrical Idle Ordered-Set (EIOS).                                                                                                 |
| $T_{TX-IDLE-SET-TO-IDLE}$        | Maximum Time to Transition to a Valid Electrical Idle after Sending an Electrical Idle Ordered-Set | 8 (max)                | 8 (max)                | ns    | After sending the required EIOS, the Transmitter must meet all Electrical Idle specifications within this time. This is measured from the end of the last UI of the last EIOS to the Tx in Electrical Idle.                                                                                  |
| $T_{TX-IDLE-TO-DIFF-DATA}$       | Maximum Time to Transition to Valid Differential Signaling after Leaving Electrical Idle           | 8 (max)                | 8 (max)                | ns    | Maximum time to transition to valid differential signaling, after leaving Electrical Idle. This is considered a de-bounce time to the Tx.                                                                                                                                                    |
| $T_{CROSSLINK}$                  | Cross-Link Random Timeout                                                                          | 1.0 (max)              | 1.0 (max)              | ms    | Random timeout that helps resolve potential conflicts in the cross-link configuration.                                                                                                                                                                                                       |
| $L_{TX-SKEW}$                    | Lane-to-Lane Output Skew                                                                           | 500 ps +<br>2 UI (max) | 500 ps +<br>4 UI (max) | ps    | Static skew between any two Lanes within a single Transmitter.                                                                                                                                                                                                                               |
| $C_{TX}$                         | AC-Coupling Capacitor                                                                              | 75 (min)<br>200 (max)  | 75 (min)<br>200 (max)  | nF    | All Transmitters shall be AC-coupled. The AC coupling is required either within the media, or within the transmitting component itself.                                                                                                                                                      |

**Notes:**

1. SSC permits a  $\pm 0, -5,000$  ppm modulation of the clock frequency, at a modulation rate not to exceed 33 kHz.
2. Specified at the measurement point into a timing and voltage compliance test load, as illustrated in [Figure 21-1](#).

**Figure 21-1. Compliance Test/Measurement Load**

3. Measurements at 5.0 GT/s require an oscilloscope with a bandwidth of  $\geq 12.5$  GHz, or equivalent, while measurements made at 2.5 GT/s require a scope with at least 6.2 GHz bandwidth. Measurements at 5.0 GT/s must de-convolve effects of the compliance test board, to yield an effective measurement at the Tx balls. 2.5 GT/s can be measured within 200 mils of the Tx device's balls; however, de-convolution is recommended. At least  $10^6$  UI of data must be acquired.
4. Transmitter jitter is measured by driving the Tx under test with a low jitter "ideal" clock and connecting the device under test (DUT) to a reference load.
5. The Tx PLL bandwidth must lie between the minimum and maximum ranges listed in [Table 21-8](#). PLL peaking must lie below the values listed in [Table 21-8](#).  
The PLL bandwidth extends from zero (0) up to the value(s) specified in [Table 21-8](#).
6. Measurement is made over at least  $10^6$  UI.
7. A single combination of PLL bandwidth and peaking is specified for 2.5 GT/s implementations. For 5.0 GT/s, two 20 combinations of PLL bandwidth and peaking are specified to permit designers to make a tradeoff between the two parameters. If the PLL's minimum bandwidth is  $\geq 8$  MHz, then up to 3.0 dB of peaking is permitted. If the PLL's minimum bandwidth is relaxed to  $\geq 5.0$  MHz, then a tighter peaking value of 1.0 dB must be met. In both cases, the maximum PLL bandwidth is 16 MHz.

Refer to Note 4.                                                                                                    |
| $Z_{RX-DIFF-DC}$                 | DC Differential Rx Impedance                                                   | 80 (min)<br>120 (max) | Not specified                                                            | $\Omega$ | Rx DC Differential mode impedance. Parameter is captured for 5.0 GHz by $RL_{RX-DIFF}$ . Refer to Note 4.                                                                                |
| $V_{RX-CM-AC-P}$                 | Rx AC Common Mode Voltage                                                      | 150 (max)             | 150 (max)                                                                | mVP      | Measured at Rx pins, into a pair of $50\Omega$ terminations into Ground. Refer to Note 5.                                                                                                |
| $Z_{RX-HIGH-IMP-DC-POS}$         | DC Input Common Mode Input Impedance for Voltage >0 during Reset or Power-Down | 50K (min)             | 50K (min)                                                                | $\Omega$ | Rx DC common mode impedance with the Rx terminations not powered, measured over the range 0 to 200 mV (with respect to Ground). Refer to Note 6.                                         |
| $Z_{RX-HIGH-IMP-DC-NEG}$         | DC Input Common Mode Input Impedance for Voltage <0 during Reset or Power-Down | 1.0K (min)            | 1.0K (min)                                                               | $\Omega$ | Rx DC common mode impedance with the Rx terminations not powered, measured over the range -150 to 0 mV (with respect to Ground). Refer to Note 6.                                        |
| $V_{RX-IDLE-DET-DIFFp-p}$        | Electrical Idle Detect Threshold                                               | 65 (min)<br>175 (max) | 65 (min)<br>175 (max)                                                    | mV       | $V_{RX-IDLE-DET-DIFFp-p} = \frac{1}{2} \times  V_{RX-D+} - V_{RX-D-} $<br>Measured at the Receiver's package pins.                                                                       |
| $T_{RX-IDLE-DET-DIFF-ENTERTIME}$ | Unexpected Electrical Idle Enter Idle Detect Threshold Integration Time        | 10 (max)              | 10 (max)                                                                 | ms       | An un-expected Electrical Idle ( $V_{RX-DIFFp-p} < V_{RX-IDLE-DET-DIFFp-p}$ ) must be recognized no longer than $T_{RX-IDLE-DET-DIFF-ENTERTIME}$ to signal an unexpected idle condition. |
| $L_{RX-SKEW}$                    | Total Lane-to-Lane Skew                                                        | 20 (max)              | 8 (max)                                                                  | ns       | Across all Lanes on a Port. Includes variation in the length of a SKIP Ordered-Set at the Rx, as well as any delay differences arising from the interconnect itself. Refer to Note 7.    |

**Notes:**

1. The four inherent timing error parameters are defined for the convenience of Rx designers, and they are measured during Receiver tolerancing.
2. Two combinations of PLL bandwidth and peaking are specified at 5.0 GT/s, to permit designers to make trade-offs between the two parameters. If the PLL's minimum bandwidth is  $\geq 8$  MHz, then up to 3.0 dB of peaking is permitted. If the PLL's minimum bandwidth is relaxed to  $\geq 5.0$  MHz, then a tighter peaking value of 1.0 dB must be met.

A PLL bandwidth extends from zero up to the value(s) defined as the minimum or maximum in [Table 21-9](#). For 2.5 GT/s, a single PLL bandwidth and peaking value of 1.5 to 22 MHz and 3.0 dB are defined.

3. Measurements must be made for both common mode and differential return loss. In both cases, the DUT must be powered up and DC-isolated, and its D+/D- inputs must be in the low-Z state.
4. The Rx DC single-ended impedance must be present when the Receiver terminations are first enabled, to ensure that the Receiver Detect occurs properly. Compensation of this impedance can start immediately, and the Rx single-ended impedance (constrained by  $RL_{RX-CM}$  to  $50\Omega \pm 20\%$ ) must be within the specified range by the time Detect is entered.
5. Common mode peak voltage is defined by the expression:

$$\max\{|(Vd+ - Vd-) - V-CMDC|\}$$

6.  $Z_{RX-HIGH-IMP-DC-NEG}$  and  $Z_{RX-HIGH-IMP-DC-POS}$  are defined, respectively, for negative and positive voltages at the input of the Receiver. Transmitter designers must comprehend the large difference between  $>0$  and  $<0$  Rx impedances when designing Receiver detect circuits.
7. The  $L_{RX-SKEW}$  parameter exists to handle repeaters that re-generate REFCLK and introduce differing numbers of skips on different Lanes.

**Table 21-10. PCI Express Differential Clock (Signal Group c) – AC and DC Characteristics**

| Symbol               | Parameter                                                                                                                    | Min  | Typ | Max   | Unit     | Notes |

| $DC_{REFCLK}$        | Input Clock Duty Cycle                                                                                                       | 45   | 50  | 55    | %        |       |
| $R_{TERM}$           | Input Parallel Termination (Single-ended)                                                                                    |      | 50  |       | $\Omega$ |       |
|                      | Input Parallel Termination (Differential)                                                                                    |      | 100 |       | $\Omega$ |       |
| PPM                  | Reference Clock Tolerance                                                                                                    | -300 |     | +300  | ppm      |       |

**Notes:**

1. *PEX\_REFCLKn/p* must be AC-coupled. Use a 0.01 to 0.1  $\mu F$  capacitor.
2. Specified at 20 to 80% points at the package balls.

## 21.7 Transmit Drive Characteristics

The Drive Current and Transmit Equalization functions are programmable, to allow for optimization of different backplane lengths and materials.

The Transmit Drive Level is programmable (5-bit, per SerDes/Lane), to provide differential swing within the range listed in [Table 21-11](#). The **SerDes Drive Level** x registers (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offsets [B98h](#) and [BA0h](#)) provide access to all 8 Lanes for Drive Level programmability.

The Transmitter also incorporates programmable (5-bit, per SerDes/Lane) de-emphasis, to provide equalization to compensate for FR4 channel effects within the range listed in [Table 21-11](#). The **Post-Cursor Emphasis Level** x registers (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offsets [BA8h](#) and [BB0h](#)) provide access to all 8 Lanes for de-emphasis programmability.

The `Transmit_Drive_Level[4:0]` and `Post-Cursor_Emphasis_Level[4:0]` bits are used together to program the differential swing, as well as the dB loss for optimum Tx drive across the intended backplane.

[Table 21-11](#) lists all possible combinations of Tx `DRV_LVL[4:0]` and `POST_CURSOR[4:0]`, to achieve minimum 800 mV transition amplitude and the resulting de-emphasis (in decibels, dB). Of these, only certain combinations yield the specified 3 to 4 dB or 5.5 to 6.5 dB de-emphasis, per the *PCI Express Base r2.0* (**highlighted in bold**). All combinations are listed, however, to provide maximum flexibility for fine-tuning the Tx drive characteristics to a specific backplane.

**Table 21-11. Tx Programmable Drive and De-Emphasis Levels**

## 21.7.1 Default Transmit Settings

Table 21-12 lists the default values of the Transmit Drive and Post-Cursor De-Emphasis levels (**SerDes Drive Level x** and **Post-Cursor Emphasis Level x** registers (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offsets **B98h** and **BA0h**, and offsets **BA8h** and **BB0h**, respectively)).

**Table 21-12. Default Transmit Settings**

| Mode (dB) | Link Speed (GT/s) | DRV_LVL [4:0] | POST_CURSOR [4:0] | Transition Amplitude (mV) | Non-Transition Amplitude (mV) | Equalization <sup>a</sup> (dB) |
|-----------|-------------------|---------------|-------------------|---------------------------|-------------------------------|--------------------------------|
| -3.5      | 2.5               | 10h           | 0Dh               | 896                       | 586                           | -3.69                          |
| -6        | 5.0               | 0Eh           | 15h               | 901                       | 415                           | -6.73 <sup>b</sup>             |

a. dB Equalization formula:

$$20 \times \log[(\text{Non-Transition Amplitude}) / (\text{Transition Amplitude})]$$

b. The -6 dB Setting is slightly larger than the maximum -6.5 dB specification, to better compensate for FR4 loss characteristics across a typical backplane application.

## 21.8 Receive Characteristics

The Receiver circuit includes programmable equalization, to further compensate for the low-pass FR4 loss characteristics of the channel.

### 21.8.1 Receive Equalization

Table 21-13 lists the programmable bits used for controlling the Receiver circuit's electrical characteristics, to mitigate the effects of signal loss and distortion across the PCB channel. The **Receiver Equalization Level x** registers (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offsets [BB8h](#) and [BBCh](#)) provide access to all 8 Lanes for Rx Equalization programmability. Figure 21-2 illustrates the Rx Equalization frequency characteristics.

**Table 21-13. Receiver Equalization Settings**

| Rx Equalization[3:0] | Equalization   |
|----------------------|----------------|
| 0h (default)         | Off            |
| 1h                   | Minimum        |
| 2h to 3h             | Low            |
| 4h to 6h             | Low to Medium  |
| 7h to 9h             | Medium         |
| Ah to Dh             | High to Medium |
| Eh to Fh             | Maximum        |

**Figure 21-2. Rx Equalization Frequency Characteristics**

## 21.8.2 Receiver Electrical Idle

The Receiver circuit contains a signal detect circuit that is used to detect signal idling at the input. The threshold to detect the idle level is programmable, using the [Signal Detect Level](#) register (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offset [BC0h](#)). A value of 00b provides the lowest signal voltage level detection threshold.

## Chapter 22 Thermal and Mechanical Specifications

### 22.1 Thermal Characteristics

The PEX 8609 does not include a heat sink. The information described in this section is based upon sample thermal performance when a heat sink is used with the PEX 8609, and is provided for reference only.

#### 22.1.1 Sample Thermal Data

Table 22-1 lists sample thermal data for the PEX 8609 at Commercial temperature, as well as a recommendation for Industrial Temperature Range support.

Table 22-1. Sample Thermal Data (15 x 15 mm<sup>2</sup> PBGA Package)<sup>a, b</sup>

| Maximum Power (Watts) <sup>c</sup> | Heat Sink (Yes/No) | Airflow Velocity (m/s) | $\Theta_{JA}$ (°C/W) |                     | $\Theta_{JC}$ (°C/W) | Heat Sink                                                                                                                             |
|------------------------------------|--------------------|------------------------|----------------------|---------------------|----------------------|---------------------------------------------------------------------------------------------------------------------------------------|

- The Maximum Operating Junction Temperature is 110°C.  
The Maximum Junction Temperature for Reliability is 125°C.
- The shaded fields provide a recommendation that allows the PEX 8609 to support Industrial Temperature Range (-40 to +85°C).
- The maximum power value listed assumes the conditions listed in Chapter 21, “Electrical Specifications,” at Gen 2 (5.0 GT/s).
- Heat Sink Part Number: Alpha Novatech W15-10W.
- Heat Sink Part Number: Alpha Novatech N19-25W.

## 22.2 General Package Specifications

Table 22-2 lists general package specifications. For a more complete list, refer to Figure 22-1.

**Table 22-2. General Package Specifications**

| Parameter           | Specification                                                          |
|---------------------|------------------------------------------------------------------------|
| Package Type        | Plastic Ball Grid Array (PBGA)                                         |
| Quantity of Balls   | 196                                                                    |
| Package Dimensions  | 15 x 15 mm <sup>2</sup><br>(approximately 1.71 ±0.19-mm high)          |
| Ball Matrix Pattern | 14 x 14 (6 x 6 mm <sup>2</sup> center area <b>reserved</b> for Ground) |
| Ball Pitch          | 1.00 mm                                                                |
| Ball Diameter       | 0.60 mm                                                                |
| Ball Spacing        | 0.40 mm                                                                |

## Mechanical Dimensions
