## Preface

The information in this data book is subject to change without notice. This PLX data book to be updated periodically as new information is made available.

## Audience

This data book provides functional details of PLX Technology's ExpressLane PEX 8609-BA 8-Lane, 8-Port PCI Express Gen 2 Switch with DMA, for hardware designers and software/firmware engineers.

## Supplemental Documentation

This data book assumes that the reader is familiar with the following documents:

- PLX Technology, Inc. (PLX), [www.plxtech.com](http://www.plxtech.com)
  - The [PLX PEX 8609 Toolbox](#) includes this data book and other supporting documentation, such as errata, and design and application notes.
- The Institute of Electrical and Electronics Engineers, Inc. (IEEE), [www.ieee.org](http://www.ieee.org)
  - *IEEE Standard 1149.1-1990, IEEE Standard Test Access Port and Boundary-Scan Architecture*
  - *IEEE Standard 1149.1a-1993, IEEE Standard Test Access Port and Boundary-Scan Architecture*
  - *IEEE Standard 1149.1-1994, Specifications for Vendor-Specific Extensions*
  - *IEEE Standard 1149.6-2003, IEEE Standard Test Access Port and Boundary-Scan Architecture Extensions*
- Intel Corporation, [www.intel.com](http://www.intel.com)
  - [PHY Interface for the PCI Express Architecture, Version 2.00](#)
- NXP Semiconductors, [www.standardics.nxp.com](http://www.standardics.nxp.com)
  - [The I2C-Bus Specification, Version 2.1](#)
- PCI Special Interest Group (PCI-SIG), [www.pcisig.com](http://www.pcisig.com)
  - *PCI Local Bus Specification, Revision 3.0*
  - *PCI Bus Power Management Interface Specification, Revision 1.2*
  - *PCI to PCI Bridge Architecture Specification, Revision 1.2*
  - *PCI Express Base Specification, Revision 1.0a*
  - *PCI Express Base Specification, Revision 1.1*
  - *PCI Express Base Specification, Revision 2.0*
  - *PCI Express Base Specification, Revision 2.0 Errata*
  - *PCI Express Card Electromechanical Specification, Revision 2.0*
  - *PCI Express Mini Card Electromechanical Specification, Revision 1.1*
  - [PCI Express Architecture PCI Express Jitter and BER White Paper, Revision 1.0](#)
- Personal Computer Memory Card International Association (PCMCIA), [www.pcmcia.org](http://www.pcmcia.org)
  - *ExpressCard Standard Release 1.0*
- PXI Systems Alliance (PXI), [www.pxisa.org](http://www.pxisa.org)
  - *PXI-5 PXI Express Hardware Specification, Revision 1.0*
- SBS Implementers Forum, [smbus.org](http://smbus.org)
  - *System Management Bus (SMBus) Specification, Version 2.0*

**Note:** In this data book, shortened titles are associated with the previously listed documents.  
The following table lists these abbreviations.

| Abbreviation                                           | Document                                                                 |
|--------------------------------------------------------|--------------------------------------------------------------------------|
| PCI r3.0                                               | PCI Local Bus Specification, Revision 3.0                                |
| PCI Power Mgmt. r1.2                                   | PCI Bus Power Management Interface Specification, Revision 1.2           |
| PCI-to-PCI Bridge r1.2                                 | PCI to PCI Bridge Architecture Specification, Revision 1.2               |
| PCI Express Base r1.0a                                 | PCI Express Base Specification, Revision 1.0a                            |
| PCI Express Base r1.1                                  | PCI Express Base Specification, Revision 1.1                             |
| PCI Express Base r2.0                                  | PCI Express Base Specification, Revision 2.0                             |
| PCI ExpressCard CEM r2.0                               | PCI Express Card Electromechanical Specification, Revision 2.0           |
| PCI ExpressCard Mini CEM r1.1                          | PCI Express Mini Card Electromechanical Specification, Revision 1.1      |
| IEEE Standard 1149.1-1990                              | IEEE Standard Test Access Port and Boundary-Scan Architecture            |
| IEEE Standard 1149.6-2003                              | IEEE Standard Test Access Port and Boundary-Scan Architecture Extensions |
| I <sup>2</sup> C Bus v2.1<br>I2C Bus v2.1 <sup>a</sup> | The I <sup>2</sup> C-Bus Specification, Version 2.1                      |
| SMBus v2.0                                             | System Management Bus (SMBus) Specification, Version 2.0                 |

- a. Due to formatting limitations, the specification name may appear without the superscripted “2” in its title.

## Terms and Abbreviations

The following table lists common terms and abbreviations used in this data book. Terms and abbreviations defined in the *PCI Express Base r2.0* are not included in this table.

| Terms and Abbreviations | Definitions                                                                                                                                                                                         |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 8b/10b                  | Data-encoding scheme used on data transferred across a Link that is operating at either Gen 1 or Gen 2 Link speed (2.5 or 5.0 GT/s, respectively).                                                  |
| ACK                     | Acknowledge Control Packet. Control packet used by a destination to acknowledge data packet receipt. Signal that acknowledges signal receipt.                                                       |
| AMCAM                   | Address-mapping CAM that determines a memory Request route. Contains mirror copies of the PCI-to-PCI bridge <b>Memory Base</b> and <b>Memory Limit</b> registers in the switch.                     |
| ARI                     | Alternative Routing-ID Interpretation.                                                                                                                                                              |
| BAR                     | Base Address register.                                                                                                                                                                              |
| BER                     | Bit error rate.                                                                                                                                                                                     |
| BusNoCAM                | Bus Number-mapping CAM that determines the Completion route. Contains mirror copies of the PCI-to-PCI bridge <b>Secondary Bus Number</b> and <b>Subordinate Bus Number</b> registers in the switch. |
| CAM                     | Content-Addressable Memory.                                                                                                                                                                         |
| CDR                     | Clock Data Recovery.                                                                                                                                                                                |
| CRC                     | Cyclic Redundancy Check.                                                                                                                                                                            |
| CSRs                    | Configuration Space registers.                                                                                                                                                                      |
| Data MRd                | Data Memory Read. Reading from the Source address, to gather data to transfer.                                                                                                                      |
| Data MWr                | Data Memory Write. Writing to the Destination address, to transfer data that was gathered with a Read.                                                                                              |
| Descriptor              | 16 bytes of information that describes the DMA, <i>such as</i> the Source address to read, Destination address to write, and total Transfer size.                                                   |
| DLL                     | Data Link Layer.                                                                                                                                                                                    |
| DMA                     | Direct Memory Access.                                                                                                                                                                               |
| DMA Ring                | Physical location where the DMA Descriptors reside. When the last Descriptor is done, the pointer automatically moves to the location of the first Descriptor, creating a DMA Descriptor Ring.      |
| Downstream Device       | Device that is connected to a downstream Port.                                                                                                                                                      |
| Downstream Port         | Port that is used to communicate with a device below it within the system hierarchy. A switch can have one or more downstream Ports.                                                                |
| ECC                     | Error-Correcting Code.                                                                                                                                                                              |
| ECRC                    | End-to-end Cyclic Redundancy Check.                                                                                                                                                                 |
| EIOS                    | Electrical Idle Ordered-Set.                                                                                                                                                                        |
| Electrical Idle         | Transmitter is in a High-Impedance state (+ and - are both at common mode voltage).                                                                                                                 |
| EP                      | Endpoint.                                                                                                                                                                                           |
| FC                      | Flow Control.                                                                                                                                                                                       |
| Field                   | Multiple register bits that are combined for a single function.                                                                                                                                     |
| GPIO                    | General-Purpose Input/Output.                                                                                                                                                                       |
| GT/s                    | Giga-Transfers per second.                                                                                                                                                                          |
| Half Station            | Internal hardware processing partition of Even- or Odd-numbered (Even or Odd) Ports.                                                                                                                |

| Terms and Abbreviations | Definitions                                                                                                                                                                                                                                                                       |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| INCH                    | Ingress Credit Handler.                                                                                                                                                                                                                                                           |
| InitFC                  | Initialization Flow Control.                                                                                                                                                                                                                                                      |
| IOCAM                   | I/O Address-mapping CAM that determines an I/O Request route. Contains mirror copies of the PCI-to-PCI bridge <b>I/O Base</b> and <b>I/O Limit</b> registers in the switch.                                                                                                       |
| JTAG                    | Joint Test Action Group.                                                                                                                                                                                                                                                          |
| Lane                    | A bidirectional pair of differential PCI Express I/O signals.                                                                                                                                                                                                                     |
| LCRC                    | Link Cyclic Redundancy Check.                                                                                                                                                                                                                                                     |
| Link Interface          | Primary side of the NT Port, connects to external device pins. The secondary side of the NT Port is called the <i>NT Port Virtual Interface</i> , and connects to the internal virtual PCI Express interface.                                                                     |
| Local                   | Reference to PCI Express attributes ( <i>such as credits</i> ) that belong to the PCI Express Link logic.                                                                                                                                                                         |
| LTSSM                   | Link Training and Status State Machine.                                                                                                                                                                                                                                           |
| LUT                     | Lookup Table.                                                                                                                                                                                                                                                                     |
| MRL                     | Manually operated Retention Latch.                                                                                                                                                                                                                                                |
| NACK                    | Negative Acknowledge. Used in the SMBus-related content.                                                                                                                                                                                                                          |
| NAK                     | Negative Acknowledge.                                                                                                                                                                                                                                                             |
| N_FTS                   | Number of Fast Training Sequences field in Training Sets.                                                                                                                                                                                                                         |
| NT                      | Non-Transparent. A bridging technique used in the PCI Express Switch to isolate Memory spaces by presenting the processor as an endpoint rather than another memory system. The PEX 8609 supports one NT Port.                                                                    |
| Partial Completion      | In PCI Express, a single Read can have one or more Completions with data. If more than one Completion is returned, they are referred to as <i>Partial Completions</i> .                                                                                                           |
| PCI Express Link Logic  | Functional unit that provides the PCI Express conforming system interface. Includes the Serializer/De-Serializer (SerDes) hardware interface modules and PCI Express interface, which provides the Physical Layer (PHY), Data Link Layer (DLL), and Transaction Layer (TL) logic. |
| PEC                     | Packet Error Code.                                                                                                                                                                                                                                                                |
| PEX                     | PCI Express.                                                                                                                                                                                                                                                                      |
| PHY                     | Physical Layer.                                                                                                                                                                                                                                                                   |
| PIPE                    | PHY Interface for PCI Express architecture.                                                                                                                                                                                                                                       |
| PLL                     | Phase-Locked Loop.                                                                                                                                                                                                                                                                |
| PM                      | Power Management.                                                                                                                                                                                                                                                                 |
| PME                     | Power Management Event.                                                                                                                                                                                                                                                           |
| Port                    | Interface to a group of SerDes and supporting logic that is capable of creating a Link, for communication with another Port.                                                                                                                                                      |
| P-P                     | PCI-to-PCI.                                                                                                                                                                                                                                                                       |
| PRBS                    | Pseudo-Random Bit Sequence.                                                                                                                                                                                                                                                       |
| QoS                     | Quality of Service.                                                                                                                                                                                                                                                               |
| RAS                     | Reliability, Availability, and Serviceability.                                                                                                                                                                                                                                    |
| RoHS                    | Restrictions on the use of certain Hazardous Substances (RoHS) Directive.                                                                                                                                                                                                         |
| RR                      | Round-Robin scheduling.                                                                                                                                                                                                                                                           |

| SerDes                  | Serializer/De-Serializer. A high-speed differential-signaling parallel-to-serial and serial-to-parallel conversion logic attached to Lane pads.                                                                                                                                                                                                                                                 |
| SMBus                   | System Management Bus.                                                                                                                                                                                                                                                                                                                                                                          |
| SPI                     | Serial Peripheral Interface.                                                                                                                                                                                                                                                                                                                                                                    |
| SSC                     | Spread-Spectrum Clock.                                                                                                                                                                                                                                                                                                                                                                          |
| Sticky Bits             | Register bits in which the current values are unchanged by a Hot Reset, Link Down event, or Secondary Bus Reset, while the switch is powered. Sticky bits are reset to default values by a Fundamental Reset. Applies to ROS, RW1CS, and RWS CSR types, and sometimes HwInit. (Refer to <a href="#">Table 14-5, “Register Types, Grouped by User Accessibility,”</a> for CSR type definitions.) |
| Sticky State            | Condition that causes a state machine to be stuck in a particular state, unable to make forward progress.                                                                                                                                                                                                                                                                                       |
| TC                      | Traffic Class.                                                                                                                                                                                                                                                                                                                                                                                  |
| TL                      | Transaction Layer.                                                                                                                                                                                                                                                                                                                                                                              |
| TLC                     | Transaction Layer Control. The module performing PCI Express Transaction Layer functions.                                                                                                                                                                                                                                                                                                       |
| TLP                     | Transaction Layer Packet. PCI Express packet formation and organization.                                                                                                                                                                                                                                                                                                                        |
| Transparent             | Refers to standard PCI Express upstream-to-downstream routing protocol.                                                                                                                                                                                                                                                                                                                         |
| TS1                     | Type 1 Training Sequence Ordered-Set.                                                                                                                                                                                                                                                                                                                                                           |
| TS2                     | Type 2 Training Sequence Ordered-Set.                                                                                                                                                                                                                                                                                                                                                           |
| Tx                      | Transceiver.                                                                                                                                                                                                                                                                                                                                                                                    |
| UI                      | Unit Interval – 400 ps at 2.5 GT/s, 200 ps at 5.0 GT/s.                                                                                                                                                                                                                                                                                                                                         |
| Upstream Device         | Device that is connected to the upstream Port.                                                                                                                                                                                                                                                                                                                                                  |
| Upstream Port           | Port that is used to communicate with a device above it within the system hierarchy.                                                                                                                                                                                                                                                                                                            |
| UTP                     | User Test Pattern.                                                                                                                                                                                                                                                                                                                                                                              |
| VC                      | Virtual Channel. The PEX 8609 supports two Virtual Channels, VC0 and VC1.                                                                                                                                                                                                                                                                                                                       |
| VCO                     | Voltage-Controlled Oscillator.                                                                                                                                                                                                                                                                                                                                                                  |
| Vector                  | Address and data.                                                                                                                                                                                                                                                                                                                                                                               |
| Virtual Interface       | Secondary side of the NT Port, connects to the internal virtual PCI Express interface.                                                                                                                                                                                                                                                                                                          |
| WRR                     | Weighted Round-Robin scheduling.                                                                                                                                                                                                                                                                                                                                                                |

## Data Book Notations and Conventions

| Notation / Convention        | Description                                                                                                                                                                                                                                                                                                                                 |
|------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">Blue text</a>    | Indicates that the text is hyperlinked to its description elsewhere in the data book. Left-click the blue text to learn more about the hyperlinked information. This format is often used for register names, register bit and field names, register offsets, chapter and section titles, figures, and tables.                              |
| PEX_XXXn[x]<br>PEX_XXXp[x]   | When the signal name appears in all CAPS, with the primary Port description listed first, field [x] indicates the number associated with the signal balls/pads assigned to a specific SerDes module/Lane. The lowercase “n” (negative) or “p” (positive) suffix indicates the differential pair of signals, which are always used together. |
| # = Active-Low signals       | Unless specified otherwise, Active-Low signals are identified by a “#” appended to the term ( <i>for example</i> , PEX_PERST#).                                                                                                                                                                                                             |
| Program/code samples         | Monospace font ( <i>program or code samples</i> ) is used to identify code samples or programming references. These code samples are case-sensitive, unless specified otherwise.                                                                                                                                                            |
| command_done                 | Interrupt format.                                                                                                                                                                                                                                                                                                                           |
| <b>Command/Status</b>        | Register names.                                                                                                                                                                                                                                                                                                                             |
| <i>Parity Error Detected</i> | Register parameter [bit or field] or control function.                                                                                                                                                                                                                                                                                      |
| Upper Base Address[31:16]    | Specific Function in 32-bit register bounded by bits [31:16].                                                                                                                                                                                                                                                                               |
| Number multipliers           | k = 1,000 ( $10^3$ ) is generally used with frequency response.<br>K = 1,024 ( $2^{10}$ ) is used for Memory size references.<br>KB = 1,024 bytes.<br>M = meg.<br>= 1,000,000 when referring to frequency (decimal notation)<br>= 1,048,576 when referring to Memory sizes (binary notation)                                                |
| 255d                         | d = Suffix that identifies decimal values.                                                                                                                                                                                                                                                                                                  |
| 1Fh                          | h = Suffix that identifies hex values.<br>Each prefix term is equivalent to a 4-bit binary value (Nibble).<br>Legal prefix terms are 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, A, B, C, D, E, F.                                                                                                                                                        |
| 1010b                        | b = suffix which identifies binary notation ( <i>for example</i> , 01b, 010b, 1010b, and so forth). Not used with single-digit values of 0 nor 1.                                                                                                                                                                                           |
| 0 through 9                  | Decimal numbers, or single binary numbers.                                                                                                                                                                                                                                                                                                  |
| byte                         | Eight bits – abbreviated to “B” ( <i>for example</i> , 4B = 4 bytes).                                                                                                                                                                                                                                                                       |
| LSB                          | Least-Significant Byte.                                                                                                                                                                                                                                                                                                                     |
| lsb                          | Least-significant bit.                                                                                                                                                                                                                                                                                                                      |
| MSB                          | Most-Significant Byte.                                                                                                                                                                                                                                                                                                                      |
| msb                          | Most-significant bit.                                                                                                                                                                                                                                                                                                                       |
| DWord                        | Double-Word (32 bits) is the primary register size in these devices.                                                                                                                                                                                                                                                                        |
| QWord                        | Quad-Word (64 bits).                                                                                                                                                                                                                                                                                                                        |
| <b>Reserved</b>              | Do not modify <b>Reserved</b> bits and words. Unless specified otherwise, these bits read as 0 and must be written as 0.                                                                                                                                                                                                                    |

| <b>Chapter 2</b> | <b>Features and Applications</b>                              | <b>5</b> |
| 2.1              | Flexible and Feature-Rich 8-Lane, 8-Port Switch               | 5        |
| 2.1.1            | Highly Flexible Port Configurations                           | 5        |
| 2.1.2            | Non-Blocking Crossbar Switch Architecture                     | 5        |
| 2.1.3            | Low Packet Latency and High Performance                       | 6        |
| 2.1.3.1          | Data Payloads                                                 | 6        |
| 2.1.3.2          | Cut-Thru                                                      | 6        |
| 2.1.4            | Virtual Channels and Traffic Classes                          | 7        |
| 2.1.5            | Port Arbitration                                              | 7        |
| 2.1.6            | End-to-End Packet Integrity                                   | 7        |
| 2.1.7            | Configuration Flexibility                                     | 7        |
| 2.1.8            | Interoperability                                              | 8        |
| 2.1.9            | Low Power with Granular SerDes Control                        | 8        |
| 2.1.10           | Dynamic Lane Reversal                                         | 8        |
| 2.1.11           | <i>performancePAK</i>                                         | 9        |
| 2.1.11.1         | Read Pacing                                                   | 9        |
| 2.1.11.2         | Dual Cast                                                     | 9        |
| 2.1.11.3         | Dynamic Buffer Pool                                           | 9        |
| 2.1.11.4         | Integrated Direct Memory Access Engine                        | 9        |
| 2.1.12           | <i>visionPAK</i>                                              | 10       |
| 2.1.12.1         | Performance Monitoring                                        | 10       |
| 2.1.12.2         | Error Injection                                               | 10       |
| 2.1.12.3         | SerDes Loopback                                               | 10       |
| 2.1.12.4         | SerDes Eye Capture                                            | 10       |
| 2.1.13           | Hot Plug for High Availability                                | 11       |
| 2.1.14           | Fully Compliant Power Management                              | 11       |
| 2.1.15           | General-Purpose Input/Output Signals                          | 11       |
| 2.1.16           | Non-Transparent Dual Host and Failover Support – NT Mode Only | 11       |
| 2.1.17           | Spread-Spectrum Clock Isolation                               | 11       |
| 2.2              | Applications                                                  | 12       |
| 2.2.1            | Fan-Out                                                       | 12       |
| 2.2.2            | Active-Standby Failover Model – NT and DMA Modes Only         | 13       |
| 2.2.3            | DMA in Control Planes – DMA Mode Only                         | 14       |
| 2.2.4            | Distributed Computing                                         | 15       |
| 2.2.5            | Intelligent Adapter Board Redundancy – NT Mode Only           | 16       |
| 2.2.6            | Generic Data Mover                                            | 17       |
| 2.3              | Software Usage Model                                          | 18       |
| 2.3.1            | System Configuration                                          | 18       |
| 2.3.2            | Interrupt Sources and Events                                  | 18       |

|                  |                                                                     |           |
|------------------|---------------------------------------------------------------------|-----------|
| <b>Chapter 3</b> | <b>Signal Ball Description</b>                                      | <b>19</b> |
| 3.1              | Introduction                                                        | 19        |
| 3.2              | Abbreviations                                                       | 19        |
| 3.3              | Internal Pull-Up Resistors                                          | 20        |
| 3.4              | Signal Ball Descriptions                                            | 20        |
| 3.4.1            | PCI Express Signals                                                 | 21        |
| 3.4.2            | Serial Hot Plug Signals                                             | 23        |
| 3.4.3            | Serial EEPROM Signals                                               | 24        |
| 3.4.4            | Strapping Signals                                                   | 25        |
| 3.4.5            | JTAG Interface Signals                                              | 31        |
| 3.4.6            | I <sup>2</sup> C/SMBus Slave Interface Signals                      | 32        |
| 3.4.7            | Device-Specific Signals                                             | 34        |
| 3.4.8            | External Resistor Signals                                           | 36        |
| 3.4.9            | No Connect Signals                                                  | 36        |
| 3.4.10           | Power and Ground Signals                                            | 37        |
| 3.5              | Physical Layout                                                     | 38        |
| <b>Chapter 4</b> | <b>Functional Overview</b>                                          | <b>39</b> |
| 4.1              | Hardware Architecture                                               | 39        |
| 4.1.1            | Port Functions                                                      | 40        |
| 4.1.1.1          | Port Configurations                                                 | 40        |
| 4.1.1.2          | Port Numbering                                                      | 41        |
| 4.2              | PCI Express Link Functional Description                             | 42        |
| 4.3              | Physical Layer                                                      | 43        |
| 4.3.1            | Physical Layer Features                                             | 43        |
| 4.3.2            | Physical Layer Status and Command Registers                         | 44        |

| <b>PCI-Compatible Type 1 Configuration Header</b>      |            |
| <b>Registers (Offsets 00h – 3Ch)</b>                   | <b>218</b> |
| 14-1. 00h PCI Configuration ID                         | 218        |
| 14-2. 04h PCI Command/Status                           | 219        |
| 14-3. 08h PCI Class Code and Revision ID               | 222        |
| 14-4. 0Ch Miscellaneous Control                        | 223        |
| 14-5. 10h Base Address 0                               | 224        |
| 14-6. 14h Base Address 1                               | 225        |
| 14-7. 18h Bus Number                                   | 225        |
| 14-8. 1Ch Secondary Status, I/O Limit, and I/O Base    | 226        |
| 14-9. 20h Memory Base and Limit                        | 228        |
| 14-10. 24h Prefetchable Memory Base and Limit          | 229        |
| 14-11. 28h Prefetchable Memory Upper Base Address      | 230        |
| 14-12. 2Ch Prefetchable Memory Upper Limit Address     | 230        |
| 14-13. 30h I/O Upper Base and Limit Address            | 231        |
| 14-14. 34h Capability Pointer                          | 231        |
| 14-15. 38h Expansion ROM Base Address                  | 231        |
| 14-16. 3Ch Bridge Control and PCI Interrupt Signal     | 232        |
| <b>PCI Power Management Capability Registers</b>       |            |
| <b>(Offsets 40h – 44h)</b>                             | <b>235</b> |
| 14-17. 40h PCI Power Management Capability             | 235        |
| 14-18. 44h PCI Power Management Status and Control     | 236        |
| <b>MSI Capability Registers</b>                        |            |
| <b>(Offsets 48h – 64h)</b>                             | <b>238</b> |
| 14-19. 48h MSI Capability                              | 239        |
| 14-20. 4Ch MSI Address                                 | 240        |
| 14-21. 50h MSI Upper Address                           | 240        |
| 14-22. 54h MSI Data                                    | 240        |
| 14-23. 58h MSI Mask                                    | 241        |
| 14-24. 5Ch MSI Status                                  | 242        |
| <b>PCI Express Capability Registers</b>                |            |
| <b>(Offsets 68h – A0h)</b>                             | <b>243</b> |
| 14-25. 68h PCI Express Capability List and Capability  | 244        |
| 14-26. 6Ch Device Capability                           | 245        |
| 14-27. 70h Device Status and Control                   | 247        |
| 14-28. 74h Link Capability                             | 249        |
| 14-29. 78h Link Status and Control                     | 252        |
| 14-30. 7Ch Slot Capability                             | 255        |
| 14-31. 80h Slot Status and Control                     | 258        |
| 14-32. 8Ch Device Capability 2                         | 264        |
| 14-33. 90h Device Status and Control 2                 | 264        |
| 14-34. 98h Link Status and Control 2                   | 265        |
| <b>Subsystem ID and Subsystem Vendor ID Capability</b> |            |
| <b>Registers (Offsets A4h – FCh)</b>                   | <b>267</b> |
| 14-35. A4h Subsystem Capability                        | 267        |
| 14-36. A8h Subsystem ID and Subsystem Vendor ID        | 267        |

**Device Serial Number Extended Capability Registers**

|                                                             |            |
|-------------------------------------------------------------|------------|
| <b>(Offsets 100h – 134h)</b>                                | <b>268</b> |
| 14-37. 100h Device Serial Number Extended Capability Header | 268        |
| 14-38. 104h Serial Number (Lower DW)                        | 269        |
| 14-39. 108h Serial Number (Upper DW)                        | 269        |

**Power Budget Extended Capability Registers**

|                                                     |            |
|-----------------------------------------------------|------------|
| <b>(Offsets 138h – 144h)</b>                        | <b>270</b> |
| 14-40. 138h Power Budget Extended Capability Header | 270        |
| 14-41. 13Ch Data Select                             | 271        |
| 14-42. 140h Power Budget Data                       | 271        |
| 14-43. 144h Power Budget Capability                 | 272        |

**Virtual Channel Extended Capability Registers**

|                                                        |            |
|--------------------------------------------------------|------------|
| <b>(Offsets 148h – 1BCh)</b>                           | <b>273</b> |
| 14-44. 148h Virtual Channel Extended Capability Header | 273        |
| 14-45. 14Ch Port VC Capability 1                       | 274        |
| 14-46. 150h Port VC Capability 2                       | 275        |
| 14-47. 154h Port VC Status and Control                 | 275        |
| 14-48. 158h VC0 Resource Capability                    | 276        |
| 14-49. 15Ch VC0 Resource Control                       | 277        |
| 14-50. 160h VC0 Resource Status                        | 277        |
| 14-51. 164h VC1 Resource Capability                    | 278        |
| 14-52. 168h VC1 Resource Control                       | 278        |
| 14-53. 16Ch VC1 Resource Status                        | 279        |

**WRR Port Arbitration Table Registers**

|                                                        |            |
|--------------------------------------------------------|------------|
| <b>(Offsets 1A8h – 1BCh)</b>                           | <b>280</b> |
| 14-54. 1A8h WRR Port Arbitration Table Phases 0 to 7   | 281        |
| 14-55. 1ACh WRR Port Arbitration Table Phases 8 to 15  | 281        |
| 14-56. 1B0h WRR Port Arbitration Table Phases 16 to 23 | 282        |
| 14-57. 1B4h WRR Port Arbitration Table Phases 24 to 31 | 282        |

**Device-Specific Registers**

|                              |            |
|------------------------------|------------|
| <b>(Offsets 1C0h – 51Ch)</b> | <b>283</b> |
|------------------------------|------------|

**Device-Specific Registers – Error Checking and Debug**

|                                                               |            |
|---------------------------------------------------------------|------------|
| <b>(Offsets 1C0h – 1FCh)</b>                                  | <b>284</b> |
| 14-58. 1C0h Device-Specific Error Status for Egress ECC Error | 285        |
| 14-59. 1C4h Device-Specific Error Mask for Egress ECC Error   | 289        |
| 14-60. 1C8h ECC Error Check Disable                           | 293        |
| 14-61. 1CCh Error Handler 32-Bit Error Status                 | 295        |
| 14-62. 1D0h Error Handler 32-Bit Error Mask                   | 297        |
| 14-63. 1D8h Clock Enable                                      | 299        |
| 14-64. 1DCh Debug Control                                     | 300        |
| 14-65. 1E0h Power Management Hot Plug User Configuration      | 309        |
| 14-66. 1E4h Egress Control and Status                         | 311        |
| 14-67. 1E8h Bad TLP Counter                                   | 313        |

| 18-123.                                                    | FB8h | Uncorrectable Error Status                           | 881        |
| 18-124.                                                    | FBCh | Uncorrectable Error Mask                             | 882        |
| 18-125.                                                    | FC0h | Uncorrectable Error Severity                         | 883        |
| 18-126.                                                    | FC4h | Correctable Error Status                             | 884        |
| 18-127.                                                    | FC8h | Correctable Error Mask                               | 885        |
| 18-128.                                                    | FCCh | Advanced Error Capabilities and Control              | 886        |
| 18-129.                                                    | FD0h | Header Log 0                                         | 887        |
| 18-130.                                                    | FD4h | Header Log 1                                         | 887        |
| 18-131.                                                    | FD8h | Header Log 2                                         | 887        |
| 18-132.                                                    | FDCh | Header Log 3                                         | 887        |

## 1.1 Overview

This data book describes PLX Technology's ExpressLane™ PEX 8609, a fully non-blocking, low-latency, low-cost, and low-power 8-Lane, 8-Port PCI Express Gen 2 Switch with DMA. Conforming to the *PCI Express Base r2.0*, the PEX 8609 enables users to add scalable, high-bandwidth I/O to various products, including communications platforms, servers, storage systems, embedded systems, and intelligent I/O modules. The PEX 8609's flexible hardware configuration and software programmability allows the switch to be tailored for a wide variety of applications, including fan-out, aggregation, and peer-to-peer applications.

The PEX 8609 supports multiple Port configuration options, to provide flexible solutions for optimal product design. [Figure 1-1](#) illustrates a subset of the Port configurations supported by the PEX 8609. The PEX 8609 can also support x2 Ports, by auto-negotiating its Ports to the Link width of the PCI Express device with which it is interfacing.

**Figure 1-1. Port Configuration Examples**

## 1.2 Features

The PEX 8609 supports the following features:

- 8-Port PCI Express switch
  - 8 Lanes with integrated on-chip SerDes
  - Low-power SerDes (under 90 mW per Lane)
  - Port configuration
    - 8 independent Ports
    - Choice of Link width (quantity of Lanes) per unique Link/Port – x1 or x4; x2 is also supported
    - Configurable with Strapping balls, serial EEPROM, I<sup>2</sup>C, SMBus, and/or Host software
    - Designate any Port as the *upstream Port* (Port 0 is recommended)
- High Performance
  - 80 GT/s aggregate bandwidth (5.0 GT/s/Lane x 8 SerDes x 2 (full duplex))
  - Integrated 5.0 GT/s SerDes speed negotiation, for each Port
  - Full line rate on all Ports
  - Cut-Thru latency – 140 ns for Link widths of x4 to x1
  - Non-blocking Crossbar Switch interface supports TLP bandwidth capacity of each x4 Link
  - Maximum Payload Size – 2,048 bytes
- *performancePAK*<sup>™</sup>
  - Read Pacing<sup>™</sup> (intelligent bandwidth allocation)
  - Dual Cast<sup>™</sup>
  - Dynamic Buffer Pool Architecture for faster credit updates
  - Integrated Direct Memory Access (DMA) engine
  - Four DMA channels
    - Internal Descriptor support
    - DMA function independent from Transparent switch function
- *visionPAK*<sup>™</sup>
  - Performance Monitoring
    - Per-Port Payload and Header Counters
    - Per-traffic type (Write, Read, Completion) Counters
  - PCI Express Packet Generator
    - Capable of saturating a x4 Gen 2 Link
  - Error Injection and Pseudo-Random Bit Sequence (PRBS)
  - SerDes Eye Capture
  - SerDes Loopback
- Access Control Services (ACS) – Protection mechanisms for added data integrity in peer-to-peer transactions
- Alternative Routing-ID Interpretation (ARI) – Enables virtualized systems and/or highly integrated multi-function devices
- Quality of Service (QoS) support
  - Two Virtual Channels (VC0 and VC1), per Port
  - Eight Traffic Classes (TC[7:0]), per Port
  - Weighted Round-Robin (WRR) Port and Virtual Channel (VC) arbitration

- Non-Transparent Bridging
  - Configurable Non-Transparent Port
  - Moveable *upstream Port*
  - Enables Dual-Host, Dual-Fabric, Host-Failover applications
  - Cross-link Port capability
- Reliability, Availability, Serviceability (RAS) features
  - All Transparent downstream Ports are Hot Plug-capable, through I<sup>2</sup>C (Serial Hot Plug Controller on every Port)
  - End-to-end Cyclic Redundancy Check (ECRC) and Poison bit support
  - Data path protection
  - Memory (RAM) error correction
  - Advanced Error Reporting support
  - Lane Status bits and GPIO available
  - Per-Port error diagnostics
  - Joint Test Action Group (JTAG) AC/DC boundary scan
- Spread-Spectrum Clock isolation
  - Dual-clock domain
- INTA# ([PEX\\_INTA#](#)) and FATAL ERROR ([FATAL\\_ERR#](#)) (Conventional PCI SERR# equivalent) ball support
- 19 General-Purpose Input/Output (GPIO) balls, which can be used for GPIO and/or Interrupt inputs
- Lane Status balls ([PEX\\_LANE\\_GOOD\[7:0\]#](#))
- Other PCI Express Capabilities
  - Lane reversal
  - Polarity reversal
  - Conventional PCI-compatible Link Power Management states – L0, L0s, L1, L2/L3 Ready, and L3 (with Vaux **not supported**)
  - Conventional PCI-compatible Device Power Management states – D0 and D3hot
  - Active State Power Management (ASPM)
  - Dynamic speed (2.5 or 5.0 GT/s) negotiation, for each Port
  - Dynamic Link width negotiation
- Out-of-Band Initialization options
  - Serial EEPROM
  - I<sup>2</sup>C and SMBus (7-bit Slave address with 100 Kbps)
- Testability – JTAG support for DC
- 15 x 15 mm<sup>2</sup>, 196-ball Plastic Ball Grid Array (PBGA) package
- Typical power – 1.35W (Gen 1, 2.5 GT/s) or 1.60W (Gen 2, 5.0 GT/s)
- Microsoft® Windows® Logo (WHQL)-compliant

- Compliant to the following specifications:
  - *PCI Local Bus Specification, Revision 3.0 (PCI r3.0)*
  - *PCI Bus Power Management Interface Specification, Revision 1.2 (PCI Power Mgmt. r1.2)*
  - *PCI to PCI Bridge Architecture Specification, Revision 1.2 (PCI-to-PCI Bridge r1.2)*
  - *PCI Express Base Specification, Revision 1.1 (PCI Express Base r1.1)*
  - *PCI Express Base Specification, Revision 2.0 (PCI Express Base r2.0)*
  - *PCI Express Base Specification, Revision 2.0 Errata*
  - *PCI Express Card Electromechanical Specification, Revision 2.0 (PCI ExpressCard CEM r2.0)*
  - *PCI Express Mini Card Electromechanical Specification, Revision 1.1 (PCI ExpressCard Mini CEM r1.1)*
  - *IEEE Standard 1149.1-1990, IEEE Standard Test Access Port and Boundary-Scan Architecture (IEEE Standard 1149.1-1990)*
  - *IEEE Standard 1149.1a-1993, IEEE Standard Test Access Port and Boundary-Scan Architecture*
  - *IEEE Standard 1149.1-1994, Specifications for Vendor-Specific Extensions*
  - *IEEE Standard 1149.6-2003, IEEE Standard Test Access Port and Boundary-Scan Architecture Extensions (IEEE Standard 1149.6-2003)*
  - *The I<sup>2</sup>C-Bus Specification, Version 2.1 (I<sup>2</sup>C Bus v2.1)*
  - *System Management Bus (SMBus) Specification, Version 2.0 (SMBus v2.0)*

## Chapter 2 Features and Applications

### 2.1 Flexible and Feature-Rich 8-Lane, 8-Port Switch

#### 2.1.1 Highly Flexible Port Configurations

The PLX ExpressLane PEX 8609 PCI Express Gen 2 Switch with DMA offers a maximum of eight configurable Ports. To support specific bandwidth needs, Link widths can be individually configured as any power-of-two, from x1 to x4, through auto-negotiation, hardware strapping, Host software configuration, an optional serial EEPROM, and/or the I<sup>2</sup>C Slave interface. Flexible buffer allocation, along with the PEX 8609's **flexible packet flow control**, maximizes throughput for applications where more traffic flows in the downstream, rather than upstream, direction.

The PEX 8609 supports several Port configurations. *For example*, the PEX 8609 can be used in a fan-out application, where any one Port is the upstream Port and the remaining available Lanes are divided among one, four, or seven downstream Ports, of varying Link widths. Any one Port can be designated as, or dynamically changed to be, the upstream Port (Port 0 is recommended).

#### 2.1.2 Non-Blocking Crossbar Switch Architecture

The Non-Blocking Crossbar Switch architecture is an on-chip interconnect switching fabric, which is built upon the existing PLX Switch Fabric Architecture technology. In addition to addressing simultaneous multiple flows, the Crossbar Switch architecture incorporates functions required to support an efficient PCI Express switch fabric, including:

- Deadlock avoidance
- Priority preemption
- PCI Express Ordering rules
- Packet fair queuing
- Oldest first scheduling

The Crossbar Switch interconnect physical topology is that of a packet-based Crossbar Switch fabric (internal fabric). The Crossbar Switch protocol is sufficiently flexible and robust to support a variety of embedded system requirements. The Crossbar Switch architecture basic features include:

- Multiple concurrent Data transfers
- Global ordering within the PEX 8609
- Three types of transactions – Posted, Non-Posted, and Completion (P, NP, and Cpl, respectively) – meet PCI and PCI Express Ordering and Deadlock Avoidance rules
- Optional weighting of source Ports, to support Source Port arbitration

## 2.1.3 Low Packet Latency and High Performance

The PEX 8609 architecture supports packet Cut-Thru with a maximum latency of 140 ns for Link widths of x4 to x1. This, combined with large Packet memory and Non-Blocking Internal Switch architecture, provides full line rate on all Ports for low-latency applications, *such as* communications and servers. The low latency enables applications to achieve high throughput and performance. In addition to low latency, the PEX 8609 supports a 2,048-byte [Maximum Payload Size](#), enabling users to achieve even higher throughput.

### 2.1.3.1 Data Payloads

The Data Payloads are variable length with a maximum of 2,048 bytes, as defined by the *Maximum Payload Size* field (available sizes are 128, 256, 512, 1,024, and 2,048, depending upon the quantity of enabled Ports). Read Requests **do not** include a Data Payload.

**Note:** Refer to the [Device Control](#) register *Maximum Payload Size* field (offset 70h[7:5]) for *Maximum Payload Size* Port limitations.

### 2.1.3.2 Cut-Thru

Cut-Thru mode can reduce latency, especially for longer packets, because the entire packet does not need to be stored before being forwarded. Instead, after the Header is decoded, the packet can be immediately forwarded. The PEX 8609 is designed to cut through TLPs, to and from every Port. By default, all Ports are enabled for Cut-Thru. Cut-Thru mode can be disabled for all Ports, by Clearing the [Debug Control](#) register *Cut-Thru Enable* bit (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offset 1DCh[21]).

Cut-Thru mode, if enabled, is supported for the PEX 8609's NT Port Link Interface, if the PEX 8609 is configured for NT mode.

**Note:** The [Debug Control](#) register *Cut-Thru Enable* bit affects the entire switch. If Cut-Thru is enabled, all Ports use Cut-Thru. If Cut-Thru is **not** enabled, no Ports use Cut-Thru.

**Caution:** *One of the drawbacks to using Cut-Thru mode is that the TLP is not known to be good until the last byte. If the TLP proves to be bad, the Cut-Thru packet must be discarded. If the TLP has already been forwarded to another device, that TLP will be framed with an EDB (End Data Bad), as opposed to the standard END.*

## 2.1.4 Virtual Channels and Traffic Classes

The PEX 8609 supports two Virtual Channels (VC0 and VC1) and eight Traffic Classes (TC[7:0]). VC0 and TC0 are required by the *PCI Express Base r2.0*, and configured at device start-up.

For further details, refer to [Section 8.2, “Virtual Channel Support.”](#)

## 2.1.5 Port Arbitration

The PEX 8609 supports hardware-fixed and Weighted Round-Robin (WRR) Ingress Port Arbitration. This allows fine-tuning of Quality of Service (QoS) and efficient use of Packet buffers, for better system performance. The PEX 8609 also supports:

- RR VC arbitration on the ingress Ports
- WRR VC arbitration on the egress Ports, that select between VC0 and VC1, for each egress Port

For further details, refer to [Section 8.2, “Virtual Channel Support.”](#)

## 2.1.6 End-to-End Packet Integrity

To enable designs that require **guaranteed error-free packets**, the PEX 8609 provides **End-to-end Cyclic Redundancy Check (ECRC)** protection and **Poison** bit support, as well as **Error-Correcting Code (ECC)** protection on the internal data paths and memory (RAM). ECC maintains packet integrity through the PEX 8609, by providing automatic correction of any 1-bit errors. These features are optional in the *PCI Express Base r2.0*; however, PLX provides them across its entire ExpressLane PCI Express Gen 2 switch product line.

## 2.1.7 Configuration Flexibility

The PEX 8609 provides several ways to configure its operations. *For example*, the PEX 8609 can be configured through Strapping balls, CPU Configuration Requests, an optional serial EEPROM, and/or the I<sup>2</sup>C Slave interface. Additionally, the I<sup>2</sup>C Slave interface allows for easy debug during the development phase, performance monitoring during the operation phase, and driver or software upgrade.

## 2.1.8 Interoperability

The PEX 8609 is designed to be fully compliant with the *PCI Express Base r2.0*, and is backward-compatible to the *PCI Express Base r1.1* and *PCI Express Base r1.0a*. Additionally, the switch supports **auto-negotiation**, **Lane reversal**, and **polarity reversal**, for maximum board design and board layout flexibility. All PLX ExpressLane devices undergo thorough interoperability testing at PLX's **Interoperability Lab** and compliance testing at the **PCI-SIG Compliance Workshop**, to ensure compatibility with PCI Express devices in the market.

## 2.1.9 Low Power with Granular SerDes Control

The PEX 8609 provides **low-power** capability that is fully compliant with the *PCI Express Base r2.0* and *PCI Power Mgmt. r1.2* Power Management (PM) specifications. Unused SerDes are automatically powered down, to further reduce power consumption.

The PEX 8609 supports **SerDes output software control**, to allow power and signal strength optimization within a system. The PLX SerDes implementation supports four power levels – *Off*, *Low*, *Typical*, and *High*. The SerDes block also supports **Loopback modes** and **Advanced Error Reporting**, which enables efficient system debug and management.

## 2.1.10 Dynamic Lane Reversal

The PEX 8609 supports dynamic Lane reversal during the Link training process. Lane reversal capability allows flexibility in determining board routing, so that PCI Express components can be connected without having to crisscross wires. If the wiring of Lanes to a device is reversed (on both Transmitters and Receivers), only one of the two connected devices must support Lane reversal.

Either of the outside Lanes (Transmitter and Receiver pairs) of the PEX 8609 programmed Link width must be identified as being Lane 0. During Link training, both devices on the Link negotiate the Lane numbering. During the Link Training and Status State Machine (LTSSM)'s *Configuration* state, the upstream device sends TS1 Ordered-Sets, in which each connected Lane is identified by a consecutive Lane Number, starting with Lane 0 corresponding to the physical Lane Number associated with the Port.

The Port reverses its Lane Numbers and attempts to re-train when any of the following conditions occur:

- No Receiver is detected on preferred Lane 0
- No valid Training Sets are received on preferred Lane 0 during the LTSSM's *Polling* state
- TS1 with a non-zero Lane Number Port is received on the Port's Lane 0

To confirm successful Lane Number negotiation, both devices exchange TS2 Ordered-Sets with identical Lane Numbers on each connected Lane.

## 2.1.11 ***performancePAK***

Exclusive to PLX, *performancePAK* is a suite of unique and innovative performance features that enable PLX's Gen 2 switches to be the highest-performing Gen 2 switches available in the market today. The *performancePAK* features consist of Read Pacing, Dual Cast, Dynamic Buffer Pool, and Integrated Direct Memory Access Engine.

### 2.1.11.1 **Read Pacing**

The Read Pacing feature allows users to throttle the quantity of Read Requests being made by downstream devices. When a downstream device requests several long Reads back-to-back, the Root Complex services the Read Requests from this downstream Port in a sequential order. If this Port has a narrow Link and is therefore slow in receiving these Read packets from the Root Complex, other downstream Ports may become starved, thus negatively impacting performance. This feature enhances performance by allowing for the adequate servicing of all downstream devices, by intelligent handling of Read Requests.

For further details, refer to [Section 9.6, "Read Pacing."](#)

### 2.1.11.2 **Dual Cast**

The Dual Cast feature allows for the copying of data (packets) from one ingress Port to two egress Ports, in a single transaction, allowing for higher performance in storage, security, and mirroring applications. The feature relieves the CPU from having to conduct two separate transactions, resulting in higher system performance.

For further details, refer to [Section 9.7, "Dual Cast."](#)

### 2.1.11.3 **Dynamic Buffer Pool**

The PEX 8609 uses a dynamic buffer pool for FC management, which uses a common pool of FC Credits that is shared among other Ports within a Half-Station. This shared buffer pool is user-programmable, so FC credits can be allocated among the enabled Ports, as needed. Not only does this prevent wasted buffers and inappropriate buffer assignments, any un-allocated buffers remain in the common buffer pool, which can then be used by other Ports within the same Half-Station, for faster FC credit updates.

For further details, refer to [Section 9.3.2, "Dynamic Buffering."](#)

### 2.1.11.4 **Integrated Direct Memory Access Engine**

The PEX 8609 implements an internal Direct Memory Access (DMA) engine that can be programmed to move data between two address locations. The DMA engine consists of four channels, each capable of saturating a PCI Express x8 Gen 2 Link in one direction. Once programmed, the PEX 8609's DMA engine moves the data between the source and destination. Optionally, the DMA engine can be programmed to generate an event to the Host after the DMA transfer completes.

For further details, refer to [Chapter 10, "Integrated DMA Engine – DMA Mode Only."](#)

## 2.1.12 visionPAK

Another PLX exclusive, *visionPAK* is a debug diagnostics suite of integrated hardware and software instruments that users can use to help bring their systems to market faster. *visionPAK* features consist of Performance Monitoring, Error Injection, SerDes Loopback, SerDes Eye Capture, and more.

### 2.1.12.1 Performance Monitoring

The PEX 8609's real-time performance monitoring allows users to literally “see” ingress and egress performance on each Port as traffic passes through the switch, using PLX's Software Development Kit (SDK). The monitoring is completely passive, and therefore, has no effect on overall system performance. Internal counters provide extensive granularity down to traffic and packet type, and even allow for the filtering of traffic (*that is*, count only Memory Writes).

### 2.1.12.2 Error Injection

Using the PEX 8609's Error Injection feature, users can inject malformed packets and/or Fatal errors into their system, then evaluate the system's ability to detect and recover from such errors.

### 2.1.12.3 SerDes Loopback

The PEX 8609 supports External Tx, Recovered Clock, and Recovered Data Loopback modes.

### 2.1.12.4 SerDes Eye Capture

Users can evaluate their system's signal integrity at the Physical Layer (PHY), using the PEX 8609's SerDes Eye Capture feature. Using PLX's SDK, users can view the Receiver eye width of any Lane on the PEX 8609. Users can then modify SerDes Settings and see the impact on the Receiver eye. [Figure 2-1](#) presents a screen shot of the SDK's SerDes Eye Capture feature.

Figure 2-1. PLX SDK SerDes Eye Capture Feature

## 2.1.13 Hot Plug for High Availability

Hot Plug capability allows users to replace hardware modules and perform maintenance, without having to power down the system. The PEX 8609 Hot Plug Capability and Advanced Error Reporting features make the switch suitable for **High-Availability (HA) applications**. If the PEX 8609 is used in an application where one or more of its downstream Ports connect to PCI Express slots, each Port's Serial Hot Plug Controller can be used to manage the Hot Plug event of its associated slot. Each PEX 8609 Transparent downstream Port is equipped with a **Hot Plug Control/Status** register, to support Hot Plug capability through external logic (by way of the I<sup>2</sup>C Master interface).

For further details, refer to [Chapter 12, "Hot Plug Support."](#)

## 2.1.14 Fully Compliant Power Management

The PEX 8609 supports Link (L0, L0s, L1, L2/L3 Ready, and L3) and Device (D0 and D3hot) PM states, in compliance with the *PCI Express Base r2.0* and *PCI Power Mgmt. r1.2* PM specifications.

For further details, refer to [Chapter 13, "Power Management."](#)

## 2.1.15 General-Purpose Input/Output Signals

The PEX 8609 contains 19 General-Purpose Input/Output (GPIO) balls and associated registers, that can be programmed to function as GPIO and/or Interrupt inputs. Default functionality is GPIO inputs; however, serial EEPROM, I<sup>2</sup>C/SMBus, and/or software can program the **GPIO** registers to define functionality for each I/O.

For further details, refer to the [GPIO\[30, 29, 16:0\]](#) signal descriptions in [Section 3.4.7, "Device-Specific Signals,"](#) and [Section 11.5, "General-Purpose Input/Output."](#)

## 2.1.16 Non-Transparent Dual Host and Failover Support – NT Mode Only

The PEX 8609 supports full Non-Transparent Bridging (NTB) functionality, to allow implementation of **multi-Host systems** and **intelligent I/O modules** in applications that require redundancy support, such as **communications, storage, and servers**.

NT bridges allow systems to isolate Host memory domains, by presenting the processor subsystem as an endpoint, rather than another memory system:

- **Base Address** registers (BARs) are used to translate addresses
- **Doorbell** registers are used to signal interrupts between the address domains
- **Scratchpad** registers are accessible from both address domains, to allow inter-processor communication

For further details, refer to [Chapter 15, "Non-Transparent Bridging – NT Mode Only."](#)

## 2.1.17 Spread-Spectrum Clock Isolation

The PEX 8609 supports Dual Clock domains. This feature allows the buffer inside the PEX 8609 to become part of two systems with different system clocks, one of which can implement Spread-Spectrum Clocking. The constant clock input must follow the clock requirements defined in the *PCI Express Base r2.0* ( $\pm 300$  ppm).

For further details, refer to [Chapter 19, "Dual Clocking Support."](#)

## 2.2 Applications

Suitable for **fan-out**, **control plane applications**, and **embedded systems**, as well as **intelligent I/O applications**, the PEX 8609 can be configured for a wide variety of form factors and applications.

### 2.2.1 Fan-Out

The PEX 8609, with its high Port count and flexible configurations, allows user-specific tuning to a variety of **Host-centric**, as well as **Peer-to-Peer**, applications.

In the example illustrated in [Figure 2-2](#), the PEX 8609 would typically have a 1-Lane upstream Port, and as many as seven downstream Ports. The downstream Ports provide x1 PCI Express connectivity to the endpoints. With its eight Ports, the PEX 8609 can provide fan-out connectivity to up to seven PCI Express devices. [Figure 2-2](#) also illustrates how some of the Ports can be bridged, to provide **PCI slots or generic devices** through the use of the PLX ExpressLane **PEX 8311** and **PEX 8112** PCI Express bridges. The PEX 8609's DMA engine can alternatively be used for Data transfers between the ASICs, FPGAs, and the Host.

Figure 2-2. Fan-In/Fan-Out Usage

## 2.2.2 Active-Standby Failover Model – NT and DMA Modes Only

The PEX 8609 supports applications requiring **Host failover** applications through the **Non-Transparency Bridging (NTB)** and **DMA** features. Figure 3 illustrates a Dual-Host system with an active and standby processor configuration. The redundancy of the Host and fabric can be achieved through the PEX 8609's NTB function. Additionally, the PEX 8609's DMA engine can be used to mirror the data on both the active and standby Hosts.

### 2.2.3 DMA in Control Planes – DMA Mode Only

The PEX 8609's DMA engine can be used to perform housekeeping tasks, *such as* reading device status information from the many endpoints available, as illustrated in [Figure 2-3](#). This particular usage model allows the DMA engine to perform the many Data transfers for endpoint status that would otherwise be handled by the processor.

**Figure 2-3. PEX 8609 DMA in a Packet Router**

## 2.2.4 Distributed Computing

The PEX 8609 is well-suited for distributed computing applications, as illustrated in Figure 2-4. Once programmed, the PEX 8609's DMA engine transfers data between the servers and through the Legacy NT Port, at a high rate. The processor can therefore focus all its computing cycles, manipulating the large amounts of data received.

Figure 2-4. Distributed Computing

## 2.2.5 Intelligent Adapter Board Redundancy – NT Mode Only

The PEX 8609 supports the **Non-Transparency (NT)** feature. Figure 2-5 illustrates a Host system using an intelligent adapter board, where the adapter board CPU is isolated from the Host CPU.

The PEX 8609 NT Port allows the two CPUs to be isolated, but communicate with one another through registers designed specifically for that purpose. Moreover, the internal DMA engine can be used to copy or mirror the data between adapter boards, so that intelligent I/O adapter redundancy is achieved.

This model can be expanded to an Active-Standby Failover model. In this case, there is an Active Host and a Standby Host, ready to take over the system if the Active Host fails. The PEX 8609's DMA engine can be used to mirror the data between Hosts thus minimizing failover time.

Figure 2-5. Intelligent Adapter Board Usage

## 2.2.6 Generic Data Mover

The PEX 8609's flexible DMA engine implements **four DMA channels**, capable of saturating a PCI Express x4 Gen 2 Link. Furthermore, it supports a Descriptor Ring approach, in which the Descriptors can be placed into external Host memory or internal to the PEX 8609. The DMA engine can move data from any Port to any Port, including the same Port (*that is*, the source and destination for a DMA transfer can be the same PEX 8609 Port). [Figure 2-6](#) illustrates two PCI Express endpoints and a PEX 8609, connected through a PCI Express switch. In this example, the PCI Express endpoints take advantage of the PEX 8609's DMA capabilities, for moving data from a PCI Express Gen 2 Link to a PCI Express Gen 1 Link.

Figure 2-6. Generic Data Mover

## 2.3 Software Usage Model

From the system model viewpoint, each PCI Express Port is a virtual PCI-to-PCI bridge, with its own set of PCI Express Configuration registers. The recommended upstream Port is Port 0; however, any Port can be configured as the upstream Port through optional configuration, by way of a serial EEPROM, the I<sup>2</sup>C Slave interface, and/or Strapping balls. The BIOS and/or Host can configure the other Ports, by way of the upstream Port, using Conventional PCI enumeration.

The PEX 8609's DMA engine is implemented as a separate function in the upstream Port. That is, the PEX 8609 is a multi-function device, where Function 0 (F0) is the Transparent PCI-to-PCI Bridge function and Function 1 (F1) is the DMA Endpoint function. Although there is no special software required for a PCI-to-PCI bridge, the DMA function is an endpoint that requires a driver for programmability and functionality.

### 2.3.1 System Configuration

The virtual PCI-to-PCI bridges within the PEX 8609 are compliant to the PCI and PCI Express system models. The Configuration Space registers (CSRs) in a virtual primary/secondary PCI-to-PCI bridge are accessible by Type 0 or Type 1 Configuration Requests, through the virtual primary bus interface (matching Bus Number, Device Number, and Function Number). Assuming the Bus Number for the upstream Port is 1, the PEX 8609's BDF (Bus, Device, Function) for F0 and F1 is 1/0/0 and 1/0/1, respectively.

### 2.3.2 Interrupt Sources and Events

The PEX 8609 supports the INTx Interrupt Message type (compatible with *PCI r3.0* Interrupt signals) or Message Signaled Interrupts (MSIs), when enabled. The PEX 8609 generates interrupts/Messages for the following:

- Hot Plug or Link State events
- PCI Express Hot Plug events
- Device-Specific errors
- GPIO-generated events
- NT Doorbell-generated events
- DMA events (DMA mode only)
- Baseline and Advanced Error Reporting

Internally generated interrupts and interrupts forwarded from downstream Ports are re-mapped and collapsed at the upstream Port.

## Chapter 3 Signal Ball Description

### 3.1 Introduction

This chapter provides descriptions of the 196 PEX 8609 signal balls. The signal name, type, location, and a brief description are provided for each signal ball. A map of the PEX 8609's physical layout is also provided.

### 3.2 Abbreviations

The following abbreviations are used in the signal tables provided in this chapter.

**Table 3-1. Ball Assignment Abbreviations**

| Abbreviation             | Description                                                                                                                                     |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| #                        | Active-Low signal                                                                                                                               |
| A                        | Analog Input signal                                                                                                                             |
| APWR                     | Power (VDD10A) balls for SerDes Analog circuits                                                                                                 |
| CMLCLK_CFCn <sup>a</sup> | Spread-Spectrum differential low-voltage, high-speed, CML negative Clock inputs                                                                 |
| CMLCLK_CFCp <sup>a</sup> | Spread-Spectrum differential low-voltage, high-speed, CML positive Clock inputs                                                                 |
| CMLCLKn <sup>a</sup>     | Differential low-voltage, high-speed, CML negative Clock inputs                                                                                 |
| CMLCLKp <sup>a</sup>     | Differential low-voltage, high-speed, CML positive Clock inputs                                                                                 |
| CMLRn                    | Differential low-voltage, high-speed, CML negative Receiver inputs                                                                              |
| CMLRp                    | Differential low-voltage, high-speed, CML positive Receiver inputs                                                                              |
| CMLTn                    | Differential low-voltage, high-speed, CML negative Transmitter outputs                                                                          |
| CMLTp                    | Differential low-voltage, high-speed, CML positive Transmitter outputs                                                                          |
| CPWR                     | 1.0V Power (VDD10) balls for low-voltage Core circuits                                                                                          |
| GND                      | Common Ground (VSS) for all circuits                                                                                                            |
| I                        | Input                                                                                                                                           |
| I/O                      | Bidirectional (Input or Output)                                                                                                                 |
| I/OPWR                   | 2.5V Power (VDD25) balls for Input and Output interfaces                                                                                        |
| O                        | Output                                                                                                                                          |
| OD                       | Open Drain output                                                                                                                               |
| PLLWR                    | 2.5V Power (VDD25A) balls for Phase-Locked Loop (PLL) circuits                                                                                  |
| PU                       | Weak internal pull-up resistor                                                                                                                  |
| SerDes                   | Serializer/De-Serializer differential low-voltage, high-speed, I/O signal pairs (negative and positive)                                         |
| STRAP                    | Signals used for PEX 8609 configuration, operational mode setting, and <b>Factory Test</b> ; these signals generally are not toggled at runtime |

a. For REFCLK input, CML source is recommended; however, LVDS source is supported.

### 3.3 Internal Pull-Up Resistors

The PEX 8609 contains I/O buffers that have weak internal pull-up resistors, indicated in this chapter by PU in the signal ball tables (**Type** column). If a signal with this notation is used and no board trace is connected to the ball, the internal resistor is usually sufficient to keep the signal from toggling. However, if a signal with this notation is not used, but is connected to a board trace and is not used nor driven by an external source at all times, the internal resistors might not be sufficiently strong to hold the signal in the inactive state. In cases such as these, it is recommended that the signal be pulled or tied High to [VDD25](#) or Low to Ground ([VSS](#)), as appropriate, through a 3K $\Omega$  to 10K $\Omega$  resistor.

[Table 3-2](#) lists the internal pull-up resistor values.

**Table 3-2. Internal Resistor Values**

| Internal Resistor | Minimum | Typical | Maximum | Units    |
|-------------------|---------|---------|---------|----------|
| PU                | 74K     | 111K    | 178K    | $\Omega$ |

### 3.4 Signal Ball Descriptions

**Note:** *If there is more than one ball per signal name that includes a numbered range, the locations are listed in the same sequence in which the range is listed, starting at the top row, from left to right. For example, PEX\_PERn7 is located at B3, PEX\_PERn6 is located at B5, and so forth.*

*If there is more than one ball per signal name that does not include a numbered range (such as [VDD10](#)), the locations are listed in ascending alphanumeric order.*

The PEX 8609 signals are divided into the following groups:

- [PCI Express Signals](#)
- [Serial Hot Plug Signals](#)
- [Serial EEPROM Signals](#)
- [Strapping Signals](#)
- [JTAG Interface Signals](#)
- [I<sup>2</sup>C/SMBus Slave Interface Signals](#)
- [Device-Specific Signals](#)
- [External Resistor Signals](#)
- [No Connect Signals](#)
- [Power and Ground Signals](#)

### 3.4.1 PCI Express Signals

Table 3-3 defines the PCI Express SerDes and Control signals.

**Table 3-3. PCI Express Signals – 37 Balls**

| Signal Name   | Type    | Location                           | Description                                                                                                                                              |
|---------------|---------|------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| PEX_PERn[7:0] | CMLRn   | B3, B5, B10, B12, N12, N10, N5, N3 | <b>Negative Half of PCI Express Receiver Differential Signal Pairs (8 Balls)</b>                                                                         |
| PEX_PERp[7:0] | CMLRp   | A3, A5, A10, A12, P12, P10, P5, P3 | <b>Positive Half of PCI Express Receiver Differential Signal Pairs (8 Balls)</b>                                                                         |
| PEX_PERST#    | I<br>PU | H13                                | <b>PCI Express Reset</b><br>Used to cause a Fundamental Reset.<br>(Refer to <a href="#">Chapter 5, “Reset and Initialization,”</a> for further details.) |
| PEX_PETn[7:0] | CMLTn   | B4, B6, B9, B11, N11, N9, N6, N4   | <b>Negative Half of PCI Express Transmitter Differential Signal Pairs (8 Balls)</b>                                                                      |
| PEX_PETp[7:0] | CMLTp   | A4, A6, A9, A11, P11, P9, P6, P4   | <b>Positive Half of PCI Express Transmitter Differential Signal Pairs (8 Balls)</b>                                                                      |

**Table 3-3. PCI Express Signals – 37 Balls (Cont.)**

| Signal Name     | Type        | Location | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-----------------|-------------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PEX_REFCLKn     | CMLCLKn     | P8       | <b>Negative Half of 100-MHz PCI Express Reference Clock Input Signal Pair</b><br>When Dual Clocking is enabled, the PEX_REFCLKn and PEX_REFCLKp signal balls become the Spread-Spectrum Clocking (SSC) domain Clock signals.<br>PEX_REFCLKn must be AC-coupled.<br>Use a 0.01 to 0.1 $\mu$ F capacitor.<br>Refer to <a href="#">Chapter 19, “Dual Clocking Support,”</a> for further details.                                                                         |
| PEX_REFCLKp     | CMLCLKp     | N8       | <b>Positive Half of 100-MHz PCI Express Reference Clock Input Signal Pair</b><br>When Dual Clocking is enabled, the PEX_REFCLKn and PEX_REFCLKp signal balls become the SSC domain Clock signals.<br>PEX_REFCLKn must be AC-coupled.<br>Use a 0.01 to 0.1 $\mu$ F capacitor.<br>Refer to <a href="#">Chapter 19, “Dual Clocking Support,”</a> for further details.                                                                                                    |
| PEX_REFCLK_CFCn | CMLCLK_CFCn | A7       | <b>Negative Half of 100-MHz PCI Express Spread-Spectrum Reference Clock Input Signal Pair</b><br>When Dual Clocking is enabled, the PEX_REFCLK_CFCn and PEX_REFCLK_CFCp signal balls become the Constant Frequency Clocking (CFC) domain Clock signals.<br>Due to internal biasing, the CFC Clock input requires an AC-coupling capacitor. Use a 0.01 to 0.1 $\mu$ F capacitor.<br>Refer to <a href="#">Chapter 19, “Dual Clocking Support,”</a> for further details. |
| PEX_REFCLK_CFCp | CMLCLK_CFCp | B7       | <b>Positive Half of 100-MHz PCI Express Spread-Spectrum Reference Clock Input Signal Pair</b><br>When Dual Clocking is enabled, the PEX_REFCLK_CFCn and PEX_REFCLK_CFCp signal balls become the CFC domain Clock signals.<br>Due to internal biasing, the CFC Clock input requires an AC-coupling capacitor. Use a 0.01 to 0.1 $\mu$ F capacitor.<br>Refer to <a href="#">Chapter 19, “Dual Clocking Support,”</a> for further details.                               |

### 3.4.2 Serial Hot Plug Signals

Transparent downstream Ports can implement Hot Plug, by using external I<sup>2</sup>C I/O Expanders (one 16-pin Maxim MAX7311, NXP PCA9555, or TI PCA9555 per slot –or– one 40-pin NXP PCA9698 per two slots, provided that the PEX 8609 serial EEPROM Sets the **Power Management Hot Plug User Configuration** register *40-Pin I/O Expander Enable* bit (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offset 1E0h[17]). All Transparent downstream Ports that implement Serial Hot Plug must use the same type of I/O Expander (either 16- or 40-pin, but not both concurrently).

Table 3-4 defines the three signal balls that support Serial Hot Plug. Additionally, the PEX 8609 supports external Serial Hot Plug signals on the I<sup>2</sup>C I/O Expander. (Refer to Section 12.6.2, “I<sup>2</sup>C I/O Expander Parts Selection and Pin Definition.”)

Hot Plug signals are enabled, configured, and accessed through the Port’s **Slot Capability** and **Slot Status and Control** registers (offsets 7Ch and 80h, respectively). Also, each Port’s **Power Management Hot Plug User Configuration** register provides additional Device-Specific configuration and control.

These signals are active only for Hot Plug-capable Ports configured at start-up. For further details regarding Hot Plug, refer to Chapter 12, “Hot Plug Support.”

**Table 3-4. Serial Hot Plug Signals – 3 Balls**

| Signal Name | Type    | Location | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| SHPC_INT#   | I<br>PU | C14      | <b>Serial Hot Plug Controller Interrupt Input</b><br>Active-Low interrupt input from external I <sup>2</sup> C I/O Expanders. Used only by Serial Hot Plug-enabled Transparent downstream Ports. The I/O Expander asserts its INT# output whenever any of its inputs change state, and de-asserts its INT# output when the corresponding Input Port Data register (that changed state) is read. When the SHPC_INT# Interrupt input (connected to the INT# output of all I/O Expanders) is asserted, the I <sup>2</sup> C Master interface begins reading the Input Port registers of all I/O Expanders, and copies the values to the appropriate bits in the corresponding Port’s <b>Slot Status</b> register (offset 80h). The I <sup>2</sup> C Master interface halts the reading of I/O Expander registers when the SHPC_INT# input de-asserts.<br><b>SHPC_INT# requires an external pull-up resistor.</b><br><i>Note: SHPC_INT# is internally de-bounced, but must remain stable for at least 10 ms.</i> |

### 3.4.3 Serial EEPROM Signals

The PEX 8609 includes four signals for interfacing to a serial EEPROM, defined in [Table 3-5](#). For information regarding serial EEPROM use, refer to [Chapter 6, “Serial EEPROM Controller.”](#)

**Table 3-5. Serial EEPROM Signals – 4 Balls**

| Signal Name | Type      | Location | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------|-----------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EE_CS#      | I/O<br>PU | J13      | <b>Active-Low Serial EEPROM Chip Select Output</b><br><i>Note:</i> Although this is an I/O signal, its logical operation is output.                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| EE_DO       | I/O<br>PU | H14      | <b>PEX 8609 Input from Serial EEPROM Data Output</b><br>Should be pulled High to <a href="#">VDD25</a> .<br><i>Note:</i> Although this is an I/O signal, its logical operation is input.                                                                                                                                                                                                                                                                                                                                                                                          |
| EE_SK       | I/O<br>PU | J14      | <b>Serial EEPROM Clock Frequency Output</b><br>Programmable, by way of the <a href="#">Serial EEPROM Clock Frequency</a> register <a href="#">EepFreq[2:0]</a> field (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offset <a href="#">268h[2:0]</a> ), to the following: <ul style="list-style-type: none"> <li>• 1 MHz (default)</li> <li>• 1.98 MHz</li> <li>• 5 MHz</li> <li>• 9.62 MHz</li> <li>• 12.5 MHz</li> <li>• 15.6 MHz</li> <li>• 17.86 MHz</li> </ul> <i>Note:</i> Although this is an I/O signal, its logical operation is output. |

### 3.4.4 Strapping Signals

The PEX 8609 Strapping signals, defined in [Table 3-6](#), Set the configuration of upstream Port and NT Port assignment, Link width, Spread-Spectrum clocking, and various setup and test modes. These balls must be pulled or tied High to [VDD25](#) or Low to [VSS](#) (GND), as indicated in the table.

After a Fundamental Reset, the [Link Capability](#) (offset [74h](#), in each Port), and [Debug Control](#) and [Port Configuration](#) registers (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offsets [1DCh](#) and [574h](#), respectively) capture ball status. Strapping ball Configuration data can be changed by writing new data to these registers from the serial EEPROM. I<sup>2</sup>C can also change Strapping ball Configuration data; however, it should first Set the Port's **Even/Odd Port Disable** register *Disable Port x* bit (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port – Even Ports, offset [230h](#)[4:2, 0], and Odd Ports, offset [234h](#)[4:2, 0]), to prevent linkup and Host enumeration. Then, when I<sup>2</sup>C programming is complete, I<sup>2</sup>C should lastly Clear the upstream Port's *Disable Port x* bit, to enable linkup and allow subsequent Host enumeration.

**Table 3-6. Strapping Signals – 28 Balls**

| Signal Name         | Type | Location | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| STRAP_UPSTRM_PORTSEL[3:0] | I    | G2, H2, F1, F3 | <p><b>Strapping Signals to Select Upstream Port (4 Balls)</b></p> <p>The STRAP_UPSTRM_PORTSEL[3:0] inputs can be overridden by the serial EEPROM value for the <b>Debug Control</b> register <i>Upstream Port ID</i> field (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offset 1DCh[11:8]). <b>If the Debug Control register is programmed by serial EEPROM, that must be the first serial EEPROM entry.</b></p> <p>I<sup>2</sup>C can also change which Port is configured to be the upstream Port, by writing to the <b>Debug Control</b> register.</p> <p>I<sup>2</sup>C should first Set the Port's <b>Even/Odd Port Disable</b> register <i>Disable Port x</i> bit (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port – Even Ports, offset 230h[4:2, 0], and Odd Ports, offset 234h[4:2, 0]), to prevent linkup and Host enumeration. After I<sup>2</sup>C re-configures the PEX 8609, I<sup>2</sup>C should lastly Clear the upstream Port's <i>Disable Port x</i> bit, to enable linkup and allow subsequent Host enumeration.</p> <p>Software can also change which Port is configured to be the upstream Port, by writing to the <b>Debug Control</b> register, if the register's <i>Hardware/Software Configuration Mode Control</i> bit (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offset 1DCh[15]) is already Set.</p> <p>All other encodings are <b>reserved</b>.</p> <p>Refer to <a href="#">Section 15.10, “Port Programmability,”</a> for further details.</p> <p>LLLL = Port 0<br/> LLLH = Port 1<br/> LHLL = Port 4<br/> LHLH = Port 5<br/> LHHL = Port 6<br/> LHHH = Port 7<br/> HLLL = Port 8<br/> HLLH = Port 9</p> |

### 3.4.5 JTAG Interface Signals

The PEX 8609 includes five signals for performing Joint Test Action Group (JTAG) boundary scan, defined in [Table 3-7](#). The JTAG interface is described in [Section 20.8, “JTAG Interface.”](#)

**Table 3-7. JTAG Interface Signals – 5 Balls**

| Signal Name | Type | Location | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| JTAG_TMS    | I    | D14      | <b>JTAG Test Mode Select</b><br>Input decoded by the JTAG TAP Controller, to control test operations.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| JTAG_TRST#  | I    | C13      | <b>JTAG Test Reset</b><br>Active-Low input used to reset the Test Access Port.<br>When JTAG functionality is not used, the JTAG_TRST# input should be driven Low, or pulled Low to <b>VSS</b> (GND) through a 1.5K $\Omega$ resistor, to place the JTAG TAP Controller into the <i>Test-Logic-Reset</i> state, which disables the test logic and enables standard logic operation.<br>Alternatively, if JTAG_TRST# input is High, the JTAG TAP Controller can be placed into the <i>Test-Logic-Reset</i> state by initializing the JTAG TAP Controller's <b>Instruction</b> register to contain the <i>IDCODE</i> instruction, or by holding the JTAG_TMS input High for at least five rising edges of the JTAG_TCK input. |

### 3.4.6 I<sup>2</sup>C/SMBus Slave Interface Signals

Table 3-8 defines the five signals that support the I<sup>2</sup>C/SMBus Slave interface. For further details, refer to Chapter 7, “I<sup>2</sup>C/SMBus Slave Interface Operation.”

**Table 3-8. I<sup>2</sup>C/SMBus Slave Interface Signals – 5 Balls**

| Signal Name          | Type                   | Location               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                      |                        |                        |                                      |     |      |       |           |     |      |           |     |      |           |     |      |           |     |      |           |     |      |           |     |      |           |     |      |           |

| I2C_SCL0    | OD   | F14      | <p><b>I<sup>2</sup>C/SMBus Serial Clock Line</b></p> <p>I<sup>2</sup>C/SMBus Clock line. Data on the I<sup>2</sup>C Bus can be transferred at rates of up to 100 kbit/s (Standard mode).</p> <p><b>I2C_SCL0 requires an external pull-up resistor.</b></p> <p><i><b>Note:</b> The PEX 8609 I<sup>2</sup>C/SMBus Slave Interface can stretch the Low period of the I<sup>2</sup>C/SMBus clock while a simultaneous in-band Request that also targets PEX 8609 registers is being processed.</i></p> |
| I2C_SDA0    | OD   | F12      | <p><b>I<sup>2</sup>C/SMBus Serial Data I/O</b></p> <p>Transmits and receives I<sup>2</sup>C/SMBus data during I<sup>2</sup>C/SMBus accesses to PEX 8609 registers.</p> <p><b>I2C_SDA0 requires an external pull-up resistor.</b></p>                                                                                                                                                                                                                                                               |

### 3.4.7 Device-Specific Signals

Table 3-9 defines the Device-Specific signals – signals that are unique to the PEX 8609.

**Table 3-9. Device-Specific Signals – 30 Balls**

| Signal Name        | Type      | Location                                                                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------|-----------|-----------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FATAL_ERR#         | O         | B13                                                                         | <p><b>Fatal Error Output</b></p> <p>Asserted Low when a Fatal error is detected in the PEX 8609 and the following conditions exist (all the same conditions that are required to send a Fatal Error Message to the Host):</p> <ul style="list-style-type: none"> <li>Specific error is defined as <i>Fatal</i> in the <b>Uncorrectable Error Severity</b> register (offset FC0h), and</li> <li>Reporting of the specific error condition is enabled, not masked by the <b>Uncorrectable Error Mask</b> register's (offset FBCh) corresponding <i>Interrupt Mask</i> bit, and</li> <li><b>Device Control</b> register <i>Fatal Error Reporting Enable</i> bit (offset 70h[2]) –or– <b>PCI Command</b> register <i>SERR# Enable</i> bit (offset 04h[8]) is Set</li> </ul> <p>The <b>Device Status</b> register <i>Fatal Error Detected</i> bit (offset 70h[18]) is Set, and the specific error is flagged in the <b>Uncorrectable Error Status</b> register (offset FB8h).</p>                                                                                                                                                                                                                                                                                                                                      |
| GPIO[30, 29, 16:0] | I/O<br>PU | A2, D3, K12, N2, M2, L3, P1, P2, M1, K1, H1, J1, J4, F2, E1, E2, E3, D1, D2 | <p><b>General-Purpose I/O (19 Balls)</b></p> <p>Default functionality is determined at Fundamental Reset; however, functionality can be switched by programming the <b>GPIO</b> registers by way of serial EEPROM, I<sup>2</sup>C/SMBus, and/or software.</p> <p>GPIO[30, 29, 16:0] provide GPIO input functionality, by default, when the <b>STRAP_TESTMODE</b>[3:0] inputs, sampled at Fundamental Reset (<b>PEX_PERST#</b> input de-assertion), are a value of 1111b (Fh).</p> <p>Alternatively, when the <b>STRAP_TESTMODE</b>[3:0] inputs, sampled at Fundamental Reset, are a value of 1100b (Ch), GPIO[9:4, 1:0] function as Serial Hot Plug <b>PERST#</b> Reset outputs, by default, for the corresponding Ports that include an external I<sup>2</sup>C I/O Expander. If an external I<sup>2</sup>C I/O Expander is not present for a Port, the corresponding GPIO[9:4, 1:0] output remains Low (the Serial Hot Plug <b>PERST#</b> output for that Port is <i>not</i> de-asserted).</p> <p>If Serial Hot Plug is implemented (using external I<sup>2</sup>C I/O Expanders), it is recommended that the GPIO[9:4, 1:0] signals be strapped as Serial Hot Plug <b>PERST#</b> Reset outputs and routed to the slots, rather than using the <b>PERST#</b> outputs from the I<sup>2</sup>C I/O Expanders.</p> |

**Table 3-9. Device-Specific Signals – 30 Balls (Cont.)**

| Signal Name         | Type      | Location                                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

### 3.4.8 External Resistor Signals

**Table 3-10. External Resistor Signals – 4 Balls**

| Signal Name | Type | Location | Description                                                                                                                                                                                                                                                                           |
|-------------|------|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| REXT_A[1:0] | A    | B8, P7   | <b>External Resistor Balls (2 Balls)</b><br>One pair per SerDes block (paired with the “B” signal).<br><b>An external 1.43K<math>\Omega</math> 1% resistor must be attached between each REXT_A and REXT_B pair.</b><br><b>Do not connect to any other signal, power, nor ground.</b> |
| REXT_B[1:0] | A    | A8, N7   | <b>External Resistor Balls (2 Balls)</b><br>One pair per SerDes block (paired with the “A” signal).<br><b>An external 1.43K<math>\Omega</math> 1% resistor must be attached between each REXT_A and REXT_B pair.</b><br><b>Do not connect to any other signal, power, nor ground.</b> |

### 3.4.9 No Connect Signals

**Caution:**     *Do not connect these balls to board electrical paths.  
These balls are internally connected to the device.*

**Table 3-11. No Connect Signals – 5 Balls**

### 4.1 Hardware Architecture

The PEX 8609 is designed with a flexible, modular architecture. The eight PCI Express Lanes are connected to one another by the internal fabric to the central RAM. [Figure 4-1](#) provides a block diagram of the PEX 8609.

**Figure 4-1. PEX 8609 Block Diagram**

## 4.1.1 Port Functions

Each Port implements the *PCI Express Base r2.0* Physical, Data Link, and Transaction Layers (PHY, DLL, and TL, respectively). The PEX 8609 supports eight integrated Serializer/De-Serializer (SerDes) modules, which provide the eight PCI Express hardware interface Lanes. The Lanes can be combined, for a total of two, five, or eight Ports.

### 4.1.1.1 Port Configurations

The upstream and downstream Ports' Link widths are initially defined by the [STRAP\\_PORTCFG\[1:0\]](#) inputs, which are pulled or tied High to [VDD25](#) or Low to [VSS](#) (GND). The serial EEPROM option can be used to re-configure the Ports, with the options defined in [Table 4-1](#). Serial EEPROM configuration occurs following a Fundamental Reset, and overrides the configuration defined by the [STRAP\\_PORTCFG\[1:0\]](#) inputs at that time. Port configuration can also be changed through the I<sup>2</sup>C Slave interface. The final Link width can be automatically negotiated down from the programmed width, through Link-width negotiation for linkup to a device with fewer Lanes. The narrowest Port on one end of the Link determines the maximum Link width. Additionally, if a connection is broken on one of the Lanes, the training sequence removes the broken Lane and negotiates to a narrower Link width. A x4 Port can negotiate down to x2 or x1.

If the Port cannot train to x1 (Lane 0 is broken), the Port reverses its Lanes and attempts to retrain. *For example*, a x4 Port that cannot train to x4 attempts to negotiate down to x2 or x1; if x1 linkup fails, the Port reverses its Lanes and re-attempts linkup negotiation. Either the lowest Lane (Lane 0) or highest Lane (if Lanes are reversed) of the programmed Link width must connect to the other device's Lane 0.

Each Port can run independently at Gen 1 (2.5 GT/s) or Gen 2 (5.0 GT/s) Link speed.

[Table 4-1](#) defines the PEX 8609 Port and Lane configurations. The Lanes are assigned to each enabled Port, in sequence. Ports that are not configured nor enabled are invisible to software.

**Table 4-1. Port Configurations**

| <a href="#">STRAP_PORTCFG[1:0]</a> | Port 0 | Port 1 | Port 4 | Port 5 | Port 6 | Port 7 | Port 8 | Port 9 |
|------------------------------------|--------|--------|--------|--------|--------|--------|--------|--------|
| (default) 00b                      | x1     | x1     | x1     | x1     | x1     | x1     | x1     | x1     |
| (Lane)                             | 0      | 4      | 1      | 5      | 2      | 6      | 3      | 7      |
| 01b                                | x4     | x1     |        | x1     |        | x1     |        | x1     |
| (Lane)                             | 0-3    | 4      |        | 5      |        | 6      |        | 7      |
| 10b                                | x4     | x4     |        |        |        |        |        |        |
| (Lane)                             | 0-3    | 4-7    |        |        |        |        |        |        |

### 4.1.1.2 Port Numbering

The Port Numbers are 0, 1, and 4 through 9, as defined in [Table 4-1](#) and illustrated in [Figure 4-2](#). (Refer to [Section 4.1.1.1](#).)

The Port Numbers have a direct relationship to the downstream Ports for the PCI Device Number assigned to the internal PCI-to-PCI bridges on the internal virtual PCI Bus. *For example*, if Port 1 is a downstream Port, the PCI-to-PCI bridge associated with that Port is Device Number 1. Each downstream Device Number matches its corresponding Port Number. *For example*, if Port 0 is the upstream Port, Ports 1, and 4 through 9 are the available downstream Ports, when all Ports are enabled. The Device Numbers for the PCI-to-PCI bridges implemented on the downstream Ports are 1, and 4 through 9, respectively.

Any PEX 8609 Port can be configured as, or dynamically changed to be, the upstream Port (Port 0 is recommended). The PCI-to-PCI bridge implemented on the upstream Port does not assume a Device Number – it accepts the Device Number assigned by the upstream device. Generally, the upstream device assigns Device Number 0, according to the *PCI Express Base r2.0*.

**Note:** In [Figure 4-2](#), the downstream Port Numbers are only those defined in [Table 4-1](#).

**Figure 4-2. Port Numbering Convention Example (When Port 0 Is Upstream Port)**

## 4.2 PCI Express Link Functional Description

The PEX 8609 groups eight SerDes together, which can comprise a total of two, five, or eight Ports. (Refer to [Table 4-1](#).) The Ports forward ingress packets to the internal fabric and central RAM, and pull egress packets from the central RAM to send out of the PEX 8609.

The PEX 8609 implements the PCI Express PHY and DLL functions for each of its Ports, and aggregates traffic from these Ports onto a transaction-based, non-blocking internal crossbar fabric. All packet queuing and ordering aspects of this layer are handled by the Crossbar Switch Control blocks.

During system initialization, software initiates Configuration Requests that set up the PCI Express interfaces, Device Numbers, and Address maps across the various Ports. These maps are used to direct traffic between Ports during standard system operation. Traffic flow between Ports is supported through the central internal fabric.

At the top level, the PEX 8609 has a layered organization consisting of the PHY, DLL, and TL blocks, as illustrated in [Figure 4-3](#). The PHY and DLL blocks have Port-specific data paths (one per PCI Express Port) that operate independently of one another. The Transaction Layer Control (TLC) ingress section of the TL block aggregates traffic for all ingress Ports, then sends the traffic to the internal crossbar fabric. The TLC egress section of the TL block accepts packets, by way of the internal crossbar fabric, from all ingress Ports, and schedules them to be sent out the appropriate egress Port.

**Figure 4-3. PCI Express Block Diagram**

## 4.3 Physical Layer

The Physical Layer (PHY) converts information received from the DLL into an appropriate serialized format and transmits it across the PCI Express Link. The PHY also receives the serialized input from the Serializer/De-Serializer (SerDes), converts it to parallel data (internal Data Bus), then writes it to the Transaction Layer Control (TLC) Ingress buffer.

The PHY includes all circuitry for PCI Express Link Interface operation, including:

- Driver and Input buffers
- Parallel-to-serial and serial-to-parallel conversion
- Phase-Locked Loops (PLLs) and clock circuitry
- Impedance Matching circuitry
- Interface Initialization and Maintenance functions

### 4.3.1 Physical Layer Features

The PHY module interfaces to the PCI Express Lanes and implements the PHY functions. The quantity of available PCI Express Ports is two, five, or eight, with a cumulative Lane bandwidth of x8. PHY functions include:

- SerDes modules, which provide all functions required by the *PCI Express Base r2.0*
- User-configurable Port division
- Link widths – x1 or x4; Link width of x2 is also supported, for auto Link-width negotiation with external PCI Express Ports
- Link speeds supported
  - 2.5 GT/s
  - 5.0 GT/s
- Hardware Link training and initialization
- Hardware detection of polarity reversal
- Hardware detection of Lane reversal
- Hardware Autonomous Speed Control supported
- Dynamic Link speed control supported
- Dynamic Link width supported
- Data scrambling/de-scrambling and 8b/10b encode/decode
- Packet framing
- Loopback Master and Slave support
- Programmable test pattern with SKIP Ordered-Set insertion and return data checking
- Receiver error checking (Elastic buffer over/underflow, disparity, and symbol encoding)
- Modified Compliance Pattern support with Receiver Error Counters, per Lane
- Link state Power Management (PM) – Supports L0, L0s, L1, L2/L3 Ready, and L3 Link PM states
- Supports cross-linked upstream Port and downstream Ports

## 4.3.2 Physical Layer Status and Command Registers

The PHY operating conditions are defined in:

- [Section 14.14.2, “Device-Specific Registers – Physical Layer \(Offsets 200h – 25Ch\)”](#)
- [Section 14.16.14, “Device-Specific Registers – Physical Layer \(Offsets B80h – C30h\)”](#)
- [Section 14.16.16, “Device-Specific Registers – Physical Layer \(Offsets E40h – EFCh\)”](#)

The System Host can track the Link operating status and re-configure Link parameters, by way of these registers.

## 4.3.3 Hardware Link Interface Configuration

The PHY can include up to eight integrated SerDes modules, which are distributed among two SerDes quads (Quads 0 and 2) and provide the PCI Express hardware interface Lanes. The SerDes modules also provide all physical communication controls and functions required by the *PCI Express Base r2.0*, as well as the Links (clustered into Ports) that connect the PEX 8609 to other PCI Express devices.

The quantity of enabled Ports, and Link widths associated with those Ports, are configurable, on a Port-by-Port basis. Initial Port configuration is determined by the [STRAP\\_PORTCFG\[1:0\]](#) inputs, serial EEPROM, and/or auto Link-width negotiation. If the PEX 8609 Ports are configured using the auto-negotiation process, the Link widths can narrow or widen (by combining multiple adjacent Lanes).

## 4.4 Transaction Layer

The upper layer of the architecture is the Transaction Layer (TL). The TL assembles and disassembles TLPs, which are used to communicate transactions, *such as* Read and Write, as well as certain types of events. The TL also manages credit-based Flow Control (FC) for TLPs.

The TL supports four Address spaces – it includes the three PCI Address spaces (Configuration, Input/Output, and Memory) and adds a Message space. (Refer to [Table 4-2](#).) This specification uses Message space to support all prior sideband signals, *such as* interrupts, Power Management (PM) Requests, and so forth, as in-band Message transactions. PCI Express Message transactions are considered *virtual wires* that support *virtual pins*. As virtual wires, Assert and De-assert Messages are sent when a triggering event changes the wire's state.

**Table 4-2. Address Spaces Support Differing Transaction Types**

| Address Space | Transaction Types      | Transaction Functions                                                          |
|---------------|------------------------|--------------------------------------------------------------------------------|
| Configuration | Read/Write             | Device configuration or setup                                                  |
| Input/Output  |                        | Transfers data from/to an I/O space                                            |
| Memory        |                        | Transfers data from/to a memory location                                       |
| Message       | Baseline/Virtual Wires | General-purpose Messages<br>Event signaling (status, interrupts, and so forth) |

All Request packets requiring a Response packet are implemented as Split Transactions. Each packet has a unique identifier that enables Response packets to be directed to the correct originator. The packet format supports various forms of addressing, depending upon the transaction type – *Memory, I/O, Configuration, or Message*.

TL functions include:

- Decoding and checking rules for the incoming TLP
- Memory-Mapped Configuration Space register (CSR) access
- Checking incoming packets for malformed or unsupported packets
- Data Poisoning and end-to-end data integrity detection
- End-to-end Cyclic Redundancy Check (ECRC) of incoming packets
- Error logging and reporting for incoming packets
- TLP dispatching
- Write control to the packet RAM and packet Link List RAM
- Destination lookup and TC-VC mapping
- Shadow CSRs for BusNoCAM/IOCAM/AMCAM/TC-VC mapping
- Credit-based scheduling
- Pipelined full Split Transaction protocol
- PCI/PCI-X-compatible ordering
- Interrupt handling (INTx or Message Signaled Interrupts (MSIs))
- Power Management (PM) support
- Hot Plug and PCI Express Hot Plug event support
- Link State event support
- QoS support
- Ordering
- Ingress and Egress credit management

The hardware functions provided by the PEX 8609 to implement the *PCI Express Base r2.0* TL requirements are illustrated in [Figure 4-4](#). The blocks provide a combination of ingress and egress control, as well as the data management at each stage within the flow sequence.

**Figure 4-4. TL Controller**

### 4.4.1 Locked Transactions

The PEX 8609 understands Locked transactions; however, it does not lock the resources. This is consistent with limitations for Locked transaction use, as outlined in the *PCI r3.0* (Appendix F, “Exclusive Accesses”), and prevents potential deadlock, as well as serious performance degradation, that could occur with Locked transaction use.

### 4.4.2 Relaxed Ordering

The PEX 8609 supports Relaxed Ordering for Completions. By default, if the RO attribute is Set within a Completion, then that Completion can bypass Posted transactions, if Posted TLPs are blocked at the egress Port (due to insufficient Posted credits from the connected device). This behavior can be disabled, by Setting the **Ingress Control Shadow** register *No Special Treatment for Relaxed Ordering Traffic* field (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offset 664h[5]).

### 4.4.3 TL Transmit/Egress Protocol – End-to-End Cyclic Redundancy Check

*End-to-End Cyclic Redundancy Check (ECRC)* is an optional 32-bit field appended to the end of the outgoing packet. ECRC is calculated over the entire packet, starting with the Header and including the Data Payload, except for the *EP* bit and bit 0 of the *Type* field, which are always considered to be a value of 1 for ECRC calculations. The *ECRC* field is transmitted, unchanged, as it moves through the fabric to the Completer device. The PEX 8609 checks the ECRC on all incoming TLPs, if enabled (Port’s **Advanced Error Capabilities and Control** register *ECRC Check Enable* bit (offset FCCh[8]) is Set), and can optionally report detected errors. (When the ECRC is detected, the **Uncorrectable Error Status** register *ECRC Error Status* bit (offset FB8h[19]) can be used to log ECRC errors.)

Additionally, the PEX 8609 can optionally append ECRC to the end of internally generated TLPs, *such as* Interrupt and Error Messages, if enabled (Port’s **Advanced Error Capabilities and Control** register *ECRC Generation Enable* bit, offset FCCh[6], is Set).

### 4.4.4 TL Receive/Ingress Protocol

The ingress side TL collects and stores inbound TLP traffic in the packet RAM. The incoming data is checked for ECRC errors, valid type field, length matching the Header *Transfer Size* field, and other TLP-specific errors defined by the *PCI Express Base r2.0*.

Header and Data Payload information is forwarded to the Source Scheduler, to be routed across the internal fabric, to the egress Port. When ECRC errors are detected, the packet is discarded.

#### 4.4.5 Flow Control Credit Initialization

The initial quantity of VC0 Flow Control (FC) credits is advertised as programmed for each type of Header and Payload. After VC0 FC initialization is complete, the FC credits received are transferred to the TL egress. The TL ingress must schedule an UpdateFC Data Link Layer Packet (DLLP) for transmission, to increase the quantity of advertised credits. When enabled, the TL initiates flow credit initialization for VC1, following VC0 initialization.

#### 4.4.6 Flow Control Protocol

The PEX 8609 implements FC protocol that ensures that the switch:

- Does not transmit a TLP over a Link to a remote Receiver, unless the receiving device has sufficient VC Buffer space to accommodate the packet
- Generates FC credit updates to the remote Transmitter, to replace credits used to send TLPs to the PEX 8609

This FC is automatically managed by the hardware, and is transparent to software. Software is used only to enable additional Buffer space, to supplement the initial default buffer assignment.

The initial default FC credits, which are enabled after Link training, allow TLP traffic immediately after Link training completes. The Configuration transactions are the first transactions to use the default VC credits, to set up the initial device operating modes and capabilities.

The TL Ingress Credit Unit transmits DLLPs (referred to as *FC packets*) that update the FC to the remote Transmitter device, on a periodic basis. The DLLPs contain FC credit information that updates the Transmitter regarding the amount of available Buffer space in the PEX 8609.

The TL Egress Credit Unit receives DLLPs from the remote device, indicating the amount of Buffer space available in the remote Receiver. The unit uses this credit information to schedule the sending of TLPs to the remote device.

## 4.5 PCI-Compatible Software Model

The PEX 8609 can be thought of as a hierarchy of PCI-to-PCI bridges, with one upstream PCI-to-PCI bridge and one or more downstream PCI-to-PCI bridges connected by an internal virtual bus. (Refer to [Figure 4-5](#).) PCI-to-PCI bridges are compliant with the PCI and PCI Express system models. [Figure 4-5](#) illustrates the concept of hierarchical PCI-to-PCI bridges, with the bus in the middle being the internal virtual PCI Bus. The Configuration Space registers (CSRs) in the upstream PCI-to-PCI bridge are accessible by Type 0 Configuration Requests that target the upstream bus interface. The upstream Port captures the Type 0 Configuration Write Target Bus Number and Device Number. The upstream Port uses this Captured Bus Number and Captured Device Number as part of the Requester ID and Completer ID for the Requests and Completions generated by the upstream Port.

The CSRs in the downstream Port PCI-to-PCI bridges are accessible by Type 1 Configuration Requests received at the upstream Port that target the internal virtual PCI Bus, by having a Bus Number value that matches the upstream bridge's Secondary Bus Number value. Each downstream bridge is associated with a unique Device Number, as explained in [Section 4.1.1.2](#).

The CSRs of downstream devices are hit in two ways. If the Configuration Request matches the PEX 8609 downstream Port Secondary Bus Number, the PEX 8609 converts the Type 1 Configuration Request into a Type 0 Configuration Request. However, if the Bus Number does **not** match the Secondary Bus Number, but falls within the Subordinate Bus Number range, the Type 1 Configuration Request is forwarded out of the PEX 8609, unchanged. A Type 1 Configuration Request that targets a Bus Number that is not within range is invalid, and is terminated by the PEX 8609 upstream Port as an Unsupported Request (UR).

After all PCI devices have been located and each assigned a Bus Number and Device Number, software can assign a Memory map and I/O map. Requests (Memory or I/O) go downstream if they fall within a bridge's Base and Limit range. In the PEX 8609, each downstream bridge has its own Base and Limit. Alternatively, Requests (Memory or I/O) go upstream if they do not target anything within the upstream bridge's Base and Limit range.

Completions are routed by the Bus Number established in the Configuration registers. If the Bus Number is in the Secondary or Subordinate range, the packet goes downstream; otherwise, the packet goes upstream.

**Figure 4-5. PEX 8609 System Configuration Propagation**

THIS PAGE INTENTIONALLY LEFT BLANK.

## Chapter 5 Reset and Initialization

### 5.1 Reset

This section describes the resets that the PEX 8609 supports. (Refer to [Table 5-1.](#)) *Reset* is a mechanism that returns a device to its initial state. Reset is propagated from upstream to downstream. Hardware or software mechanisms can trigger three different levels of reset – Fundamental, Hot, or Secondary Bus (each is described in the sections that follow). The re-initialized states following a reset vary, depending upon the reset type.

**Table 5-1. Reset Summary**

| PCI Express Definition                                                                                    | Reset Source                                                                                                                                                              | Impact to Different Internal Components (upon De-Assertion)                                                                                                                                                                                                                                                                                                                                                                                                                    | Impact to Internal Registers                                                                                                                                                       |

|                                                                                                           | Upstream Port's <b>Bridge Control</b> register <i>Secondary Bus Reset</i> bit (offset 3Ch[22]) is Set                                                                     | <ul style="list-style-type: none"> <li>All downstream Ports propagate a Hot Reset</li> <li>DLL of each downstream Port is down</li> <li>TL of each downstream Port is initialized, exhibits DL_Down behavior, and drops TLP Requests that target downstream Ports</li> <li>Upstream Port TL exhibits DL_Up behavior</li> </ul>                                                                                                                                                 | Initializes downstream Ports registers to default values                                                                                                                           |

### 5.1.1 Fundamental Reset

Fundamental Reset is a hardware mechanism defined by the *PCI Express Base r2.0*, Section 6.6. Fundamental Reset input, through the `PEX_PERST#` signal, resets all Port states and Configuration registers to default conditions. Reset remains asserted, until the Port's bit is Cleared.

### 5.1.2 Hot Reset

Hot Reset is an in-band Reset that propagates from an upstream PCI Express Link to all its Transparent downstream Ports, through the Physical Layer (PHY) mechanism. The PHY mechanism communicates a reset to downstream devices through a training sequence (TS1/TS2 Ordered-Set, in which the *Hot Reset Training Control Bit* is Set). Hot Reset is also referred to as a *Soft Reset*.

A Hot Reset initializes all Ports, resets registers that are not defined as Sticky, and resets the serial EEPROM logic to reload registers (except Port Configuration registers) from serial EEPROM, if present<sup>a</sup>. Hot Reset does not reset the Clock logic, and can be caused by any of the following:

- Upstream Port PHY receives two consecutive TS1 Ordered-Sets in which the *Hot Reset Training Control Bit* is Set. Hot Reset is generated from an upstream device, *such as* by Setting its **Bridge Control** register *Secondary Bus Reset* bit (offset `3Ch[22]`).
- Upstream Port unexpectedly enters the *DL\_Down* state.  
**Exception** – If the upstream Port Link is in the L2 Link PM state and the Link goes down, the downstream Ports do **not** generate Hot Reset.
- Upstream Port PHY enters either the *Loopback* or *Disabled* state, upon receiving two consecutive TS1 or TS2 Ordered-Sets in which either the *Loopback* or *Disable Link Training Control Bit* is Set, respectively. An upstream device can generate the *Disable Link* sequence, by Setting its **Link Control** register *Link Disable* bit (offset `78h[4]`).

### 5.1.3 Secondary Bus Reset

Any virtual upstream or downstream PCI-to-PCI bridge within the PEX 8609 can reset its downstream hierarchy, by Setting the **Bridge Control** register *Secondary Bus Reset* bit (offset `3Ch[22]`).

When the *Secondary Bus Reset* bit is Set on the upstream Port, all the downstream Ports are initialized to their default states, as defined by the *PCI Express Base r2.0*. Each of the Transparent downstream Ports generates an in-band Hot Reset onto its downstream Links (the NT Port Link Interface does not generate Hot Reset). In addition, writable registers defined by the *PCI Express Base r2.0*, in all downstream Ports, are initialized to default values (upstream Port registers are not reset, and the serial EEPROM does not reload registers).

When the *Secondary Bus Reset* bit is Set on a downstream Port, that Port is reset to its default state as defined by the *PCI Express Base r2.0*, and generates an in-band Hot Reset onto its downstream Link. The registers of that downstream Port are not affected.

<sup>a</sup>. The serial EEPROM is considered to be present if it returns a non-zero value in response to an initial Read Status command of its Status register. This value is copied to the **Serial EEPROM Status** register Status Data from Serial EEPROM fields (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offset `260h[31:24]`). Serial EEPROM presence is reported in the register's *EepPrsnt[1:0]* field [`17:16`]; a value of 01b or 11b indicates that the serial EEPROM is present.

## 5.1.4 Register Bits that Affect Hot Reset

Setting the **Bridge Control** register *Secondary Bus Reset* bit (offset 3Ch[22]) generates a Hot Reset to downstream Ports and downstream devices.

## 5.1.5 Reset and Clock Initialization Timing

**Table 5-2. Reset and Clock Initialization Timing**

| Symbol | Description                                           | Typical Delay |
|--------|-------------------------------------------------------|---------------|
| td1    | REFCLK stable to PEX_Reset release time               | 100 $\mu$ s   |
| td2    | PEX_Reset release to Reset de-bounce                  | 1.32 ms       |

**Figure 5-1. Reset and Clock Initialization Timing**

## 5.2 Initialization Procedure

The PEX 8609 initialization process starts upon exit from a Fundamental Reset. There are two or more steps in the process, depending upon the availability of an external initialization serial EEPROM and I<sup>2</sup>C.

*The initialization sequence executed is as follows:*

1. PEX 8609 reads the Strapping inputs, to determine the upstream Port ([STRAP\\_UPSTRM\\_PORTSEL\[3:0\]](#)) and Lane configuration ([STRAP\\_PORTCFG\[1:0\]](#)) of each enabled Port.
2. If a serial EEPROM is present, serial EEPROM data is downloaded to the PEX 8609 Configuration registers. The configuration from the Strapping inputs can be changed by serial EEPROM data.

Alternatively, I<sup>2</sup>C can be used to program all the registers (the same as would be done with the serial EEPROM), except, if PHY or DLL register values that affect SerDes parameters or Link initialization need to be changed, those registers must be programmed by serial EEPROM, so that the values are loaded prior to initial Link training. Because I<sup>2</sup>C is relatively slow, the Links are usually up by the time the first I<sup>2</sup>C Write occurs. The first I<sup>2</sup>C command might be to block system access while the configuration is being changed, by disabling the upstream Port; Ports can be disabled by Setting the Port's **Even/Odd Port Disable** register *Disable Port x* bit (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port – Even Ports, offset [230h\[4:2, 0\]](#) and Odd Ports, [234h\[4:2, 0\]](#), respectively).

Switch configuration, including [Port Configuration](#) (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offset [574h\[1:0\]](#)) and/or upstream Port designation (**Debug Control** register *Upstream Port ID* field (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offset [1DCh\[11:8\]](#))) can be changed:

- At runtime, by software, if the **Debug Control** register *Hardware/Software Configuration Mode Control* bit (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offset [1DCh\[15\]](#)) is Set
- By I<sup>2</sup>C and/or serial EEPROM reload

If the **Debug Control** register *Upstream Port ID* field value is to be changed, the register must be written twice, with *Factory Test Only* bit [7](#) Set in the first Write, and Cleared in the second Write. Changes take effect upon subsequent Hot Reset.

**Note:** As described in [Chapter 7, “I<sup>2</sup>C/SMBus Slave Interface Operation,”](#) an external I<sup>2</sup>C Master can send the register Read/Write Requests to PEX 8609 after reset. To prevent conflict, first disable the upstream Port, by Setting the Port's *Disable Port x* bit. Restoration of the upstream Port should be the last register Write of the entire I<sup>2</sup>C programming procedure.

3. After configuration from the Strapping inputs, serial EEPROM, and/or I<sup>2</sup>C is complete, the PHY of the configured Ports attempts to bring up the Links. After both components on a Link enter the initial Link Training state, the components proceed through PHY Link initialization and then through Flow Control initialization for VC0 and VC1, preparing the DLL and TL to use the Link. following Flow Control initialization for VC0 and VC1, it is possible for VC0 and VC1 TLPs and DLL Packets (DLLPs) to be transmitted across the Link.

## 5.2.1 Default Port Configuration

The default upstream Port selection and overall Link width configuration is determined by Strapping inputs, which must be pulled or tied High to [VDD25](#) or Low to Ground ([VSS](#)), to define the default device configuration. (Refer to [Section 3.4.4, “Strapping Signals.”](#)) The configuration defined by the Strapping inputs can be changed by downloading serial EEPROM data, and/or by I<sup>2</sup>C programming followed by a Hot Reset.

## 5.2.2 Default Register Initialization

Each PEX 8609 Port defined in the Port Configuration process has a set of assigned registers that control Port activities and status during standard operation. These registers are programmed to default/initial values, as defined in:

- [Chapter 14, “Transparent Port Registers”](#)
- [Chapter 16, “NT Port Virtual Interface Registers – NT Mode Only”](#)
- [Chapter 17, “NT Port Link Interface Registers – NT Mode Only”](#)
- [Chapter 18, “DMA Interface Registers – DMA Mode Only”](#)

Following a Fundamental Reset, the basic PCI Express Support registers are initially programmed to the values specified in the *PCI Express Base r2.0*. The Device-Specific registers are programmed to the values specified in their register description tables. These registers can be changed by loading new data with the attached serial EEPROM, the I<sup>2</sup>C Slave interface, and/or by CSR accesses using Configuration or Memory Writes; however, registers identified as Read-Only (RO) **cannot** be modified by Configuration nor Memory Write Requests.

The Transparent Ports and NT Port support the following mechanisms for accessing registers by way of the TL, as described in:

- [Section 14.4.1, “PCI r3.0-Compatible Configuration Mechanism”](#)
- [Section 14.4.2, “PCI Express Enhanced Configuration Access Mechanism”](#)
- [Section 14.4.3, “Device-Specific Memory-Mapped Configuration Mechanism”](#)

For NT mode, refer also to [Section 16.3.3](#) or [Section 17.3.3, “Device-Specific Cursor Mechanism.”](#)

## 5.2.3 Device-Specific Registers

The Device-Specific registers are unique to the PEX 8609, and are not referenced in the *PCI Express Base r2.0*. The registers are organized into the following sections:

- [Section 14.14, “Device-Specific Registers \(Offsets 1C0h – 51Ch\)”](#)
- [Section 14.16, “Device-Specific Registers \(Offsets 530h – F8Ch\)”](#)

### 5.2.4 Serial EEPROM Load Time

Serial EEPROM initialization loads only the Configuration register data that is specifically programmed into the serial EEPROM. Registers that are not included in the serial EEPROM data are initialized to default register values.

Each register entry in the serial EEPROM consists of two Address bytes and four Data bytes (refer to [Section 6.4, “Serial EEPROM Data Format”](#)); therefore, each register entry (6 bytes, or 48 bits) requires 48 serial EEPROM clocks to download. Thus, at the serial EEPROM clock default frequency of 1 MHz, after initial overhead to read the [Serial EEPROM Status](#) register (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offset 260h) (16 serial EEPROM clocks, or 16  $\mu$ s), plus another 40 serial EEPROM clocks (40  $\mu$ s) to begin reading the register data, each register entry in the serial EEPROM requires 48  $\mu$ s to download. A serial EEPROM containing 50 register entries (typical configuration, assuming the serial EEPROM is programmed only with non-default register values) and clocked at 1 MHz takes approximately 5.2 ms to load (16 + 40 + 48) x 50  $\mu$ s (5,200  $\mu$ s).

To reduce the serial EEPROM initialization time, the first register entry in the serial EEPROM can increase the clock frequency, by programming the [Serial EEPROM Clock Frequency](#) register (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offset 268h), to a value of 2h (5 MHz), or 3h (9.62 MHz), if the serial EEPROM supports the higher frequency at the serial EEPROM supply voltage (typically 2.5 to 3.3V). At 5-MHz clocking, the serial EEPROM load time for 50 register entries can be reduced to approximately 575  $\mu$ s. Because the *PCI Express Base r2.0* allows a 20-ms budget for system hardware initialization, the default 1-MHz serial EEPROM clock is often sufficient when the quantity of Ports and registers programmed by serial EEPROM is relatively small.

For further details, refer to [Chapter 6, “Serial EEPROM Controller.”](#)

### 5.2.5 I<sup>2</sup>C Load Time

Initialization using I<sup>2</sup>C is slower than serial EEPROM initialization, because the I<sup>2</sup>C Slave interface operates at a lower clock frequency (100 KHz maximum) and the quantity of bits per Register access is increased (because the Device address is included in the bit stream). Writing one register using 100-KHz clocking takes approximately 830  $\mu$ s (83 clock periods).

For further details, refer to [Section 7.2, “I<sup>2</sup>C Slave Interface.”](#)

### 6.1 Overview

The PEX 8609 provides a Serial EEPROM Controller and interface to Serial Peripheral Interface (SPI)-compatible serial EEPROMs, as illustrated in [Figure 6-1](#). This interface consists of a Chip Select, Clock and Write Data outputs, and a Read Data input, and operates at a programmable frequency of up to 17.86 MHz. The PEX 8609 supports serial EEPROMs that use 1-, 2-, or 3-byte addressing (2-byte addressing is recommended); the PEX 8609 automatically determines the appropriate addressing mode.

The controller provides access to non-volatile memory. This external memory can be used for three different purposes:

- The serial EEPROM can be used to store register data, for switch configuration and initialization. When a serial EEPROM device is connected to the PEX 8609, immediately after reset, the Serial EEPROM Controller reads data from the serial EEPROM that is used to update the PEX 8609 register default values.
- System or application data can be stored into, and read from, the serial EEPROM, by software, I<sup>2</sup>C and/or SMBus, initiating random-access Read or Write Requests to the serial EEPROM.
- In NT mode, the serial EEPROM can provide up to 32 KB of Expansion ROM, for the NT Port Link Interface (default) or NT Port Virtual Interface. When software reads the Expansion ROM (starting at the Expansion ROM Base Address), the PEX 8609 reads from the serial EEPROM, to return the requested ROM image.

**Figure 6-1. Serial EEPROM Connections**

## 6.2 Features

- Detection of whether a serial EEPROM is present/not present
- Supports high-speed serial EEPROMs with Serial Peripheral Interface (SPI) interface
- Non-volatile storage for register default values loaded during Power-On Reset
- 4-byte Write/Read access to the serial EEPROM, through the upstream Port
- Serial EEPROM data format allows for loading registers by Port/Address location
- Required serial EEPROM size is dependent upon the quantity of registers being changed
- Automatic support for 1-, 2-, or 3-byte-addressable serial EEPROMs
- Manual override for quantity of serial EEPROM Address bytes
- Programmable serial EEPROM clock frequency
- Programmable serial EEPROM clock-to-chip select timings
- No Cyclic Redundancy Check (CRC), single *Valid* byte at start of serial EEPROM memory
- Supports Expansion ROM for the NT Port (**not supported** for 1-byte address serial EEPROMs)

## 6.3 Serial EEPROM Load following Upstream Port Reset

The Serial EEPROM Controller performs a serial EEPROM download when the following conditions exist:

- Serial EEPROM is present<sup>a</sup>, and
- Validation signature (first byte read from the serial EEPROM) value is **5Ah**, and
- One of the following events occur:
  - **PEX\_PERST#** is returned High, following a Fundamental Reset (*such as* a Cold or Warm Reset to the entire chip)
  - Hot Reset is received at the upstream Port (downloading upon this event can be optionally disabled, by Setting the **Debug Control** register *Disable Serial EEPROM Load on Hot Reset* and/or *Upstream Hot Reset Control* bit (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offset **1DCh**[**17** and/or **16**], respectively))
  - Upstream Port exits a **DL\_Down** state (downloading upon this event can be optionally disabled, by Setting the **Debug Control** register *Upstream Port and NT-Link DL\_Down Reset Propagation Disable* and/or *Upstream Hot Reset Control* bit (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offset **1DCh**[**20** and/or **16**], respectively))

---

*a. The serial EEPROM is considered to be present if it returns a non-zero value in response to an initial Read Status command of its Status register. This value is copied to the **Serial EEPROM Status** register Status Data from Serial EEPROM fields (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offset **260h**[**31:24**]). Serial EEPROM presence is reported in the register's **EepPrsnt**[**1:0**] field [**17:16**]; a value of 01b or 11b indicates that the serial EEPROM is present.*

## 6.4 Serial EEPROM Data Format

The data in the serial EEPROM is stored in the format defined in [Table 6-1](#). The Validation Signature byte is located in the first address. The Serial EEPROM Controller reads this byte to determine whether a valid serial EEPROM image exists versus a blank image. REG\_BYTE\_COUNT[15:0] contains the quantity of bytes of serial EEPROM data to be loaded. It is equal to the quantity of registers to be loaded times 6 (6 serial EEPROM bytes, per register). If the REG\_BYTE\_COUNT[15:0] value is not a multiple of 6, the last incomplete register entry is ignored.

For the remaining register-related locations, data is written into a 2-byte address that represents the Configuration register offset and Port Number, and the 4 bytes following are the data loaded for that Configuration register. Only Configuration register data specifically programmed into the serial EEPROM is loaded after the PEX 8609 exits reset.

[Table 6-2](#) defines the Configuration register Address format (REGADDR[15:0] from [Table 6-1](#)):

- Bits [9:0] represent bits [11:2] of the Register address
- Bits [15:10] represent the Port Number of the register selected to be programmed by serial EEPROM

Because the PEX 8609 Serial EEPROM Controller always accesses 4 bytes of serial EEPROM data (for DWord-aligned Register addresses), register offsets are stored in the serial EEPROM as DWord address values.

To determine the 2-byte serial EEPROM value that represents the PEX 8609 Port and register offset, shift the register offset 2 bits to the right (divide by 4), then OR the resulting value with the appropriate Port Identifier value from [Table 6-2](#).

*For example*, to load Port 4 register offset 1F8h, shift the address to the right by 2 bits (this becomes 07Eh) and concatenate 0001\_00b. The resulting DWord address in the serial EEPROM will be 0001\_0000\_0111\_1110b, which is 107Eh.

**Table 6-1. Serial EEPROM Data**

| Location | Value                | Description                                          |
|----------|----------------------|------------------------------------------------------|
| 0h       | 5Ah                  | Validation Signature                                 |
| 1h       | 00h                  | <b>Reserved</b>                                      |
| 2h       | REG_BYTE_COUNT (LSB) | Configuration register Byte Count (LSB)              |
| 3h       | REG_BYTE_COUNT (MSB) | Configuration register Byte Count (MSB)              |
| 4h       | REGADDR (LSB)        | 1 <sup>st</sup> Configuration Register Address (LSB) |
| 5h       | REGADDR (MSB)        | 1 <sup>st</sup> Configuration Register Address (MSB) |
| 6h       | REGDATA (Byte 0)     | 1 <sup>st</sup> Configuration Register Data (Byte 0) |
| 7h       | REGDATA (Byte 1)     | 1 <sup>st</sup> Configuration Register Data (Byte 1) |
| 8h       | REGDATA (Byte 2)     | 1 <sup>st</sup> Configuration Register Data (Byte 2) |
| 9h       | REGDATA (Byte 3)     | 1 <sup>st</sup> Configuration Register Data (Byte 3) |
| Ah       | REGADDR (LSB)        | 2 <sup>nd</sup> Configuration Register Address (LSB) |
| Bh       | REGADDR (MSB)        | 2 <sup>nd</sup> Configuration Register Address (MSB) |
| Ch       | REGDATA (Byte 0)     | 2 <sup>nd</sup> Configuration Register Data (Byte 0) |
| Dh       | REGDATA (Byte 1)     | 2 <sup>nd</sup> Configuration Register Data (Byte 1) |
| Eh       | REGDATA (Byte 2)     | 2 <sup>nd</sup> Configuration Register Data (Byte 2) |
| Fh       | REGDATA (Byte 3)     | 2 <sup>nd</sup> Configuration Register Data (Byte 3) |
| ...      | ...                  | ...                                                  |
| FFFFh    | REGDATA (Byte 3)     | Last Configuration Register Data (Byte 3)            |

**Note:** The first Configuration register programmed by the serial EEPROM **must** be the **Debug Control** register (Port 0, offset **1DCh**), serial EEPROM locations 4h through 9h, as listed in [Table 6-1](#).

**Table 6-2. Configuration Register Address Format**

| Port Number                            | REGADDR Bits [15:10] Value <sup>a</sup> | Port Identifier |
|----------------------------------------|-----------------------------------------|-----------------|
| Port 0                                 | 0000_00b                                | 0000h           |
| Port 1                                 | 0000_01b                                | 0400h           |
| Port 4                                 | 0001_00b                                | 1000h           |
| Port 5                                 | 0001_01b                                | 1400h           |
| Port 6                                 | 0001_10b                                | 1800h           |
| Port 7                                 | 0001_11b                                | 1C00h           |
| Port 8                                 | 0010_00b                                | 2000h           |
| Port 9                                 | 0010_01b                                | 2400h           |
| NT Port Link Interface                 | 1100_00b                                | C000h           |
| NT Port Virtual Interface <sup>b</sup> | 00XX_XXb                                | XX00h           |
| NT PCI-to-PCI Bridge                   | 1100_01b                                | C400h           |
| DMA CSRs                               | 1100_10b                                | C800h           |
| DMA Descriptor RAM                     | 1100_11b                                | CC00h           |

- a. Encodings not listed are **reserved**.
- b. For NT Port Virtual Interface registers, use the value for the Port Number that is configured as the NT Port (as designated by the [STRAP\\_NT\\_UPSTRM\\_PORTSEL\[3:0\]](#) inputs or **Debug Control** register *NT Port Number* field (Port 0, offset 1DCh[27:24])).

## 6.5 Serial EEPROM Initialization

After the device Reset is de-asserted, the PEX 8609 determines whether a serial EEPROM is present. The serial EEPROM is considered to be present if it returns a non-zero value in response to an initial Read Status command of its **Status** register. This value is copied to the **Serial EEPROM Status** register *Status Data from Serial EEPROM* fields (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offset 260h[31:24]). Serial EEPROM presence is reported in the register's *EepPrsnt[1:0]* field [17:16]; a value of 01b or 11b indicates that the serial EEPROM is present. A pull-up resistor on the **EE\_DO** input produces a value of FFh if a serial EEPROM is not installed.

If a serial EEPROM is detected, the first byte (validation signature) is read. If a value of 5Ah is read, it is assumed that the serial EEPROM is programmed for the PEX 8609. The serial EEPROM address width is determined while the first byte is read. If the first byte's value is not 5Ah, the serial EEPROM is blank or programmed with invalid data. In this case, no more data is read from the serial EEPROM, and the **Serial EEPROM Status** register *EepAddrWidth* field (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offset 260h[23:22]) reports a value of 00b (undetermined width).

If the *EepAddrWidth* field reports a value of 00b, any subsequent accesses to the serial EEPROM (through the PEX 8609 Serial EEPROM registers) default to a serial EEPROM address width of 1 byte unless the **Serial EEPROM Status** register *EepAddrWidth Override* bit (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offset 260h[21]) is Set. The *EepAddrWidth* field is usually Read-Only (RO); however, it is writable if the *EepAddrWidth Override* bit is Set (both can be programmed by a single Write instruction).

If the serial EEPROM contains valid data, the REG\_BYTE\_COUNT values in Bytes 2 and 3 determine the quantity of serial EEPROM locations that contain Configuration register addresses and data. Each Configuration register entry consists of 2 bytes of register Address and 4 bytes of register Write data. The REG\_BYTE\_COUNT must be a multiple of 6.

The **EE\_SK** output clock frequency is determined by the **Serial EEPROM Clock Frequency** register *EepFreq[2:0]* field (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offset 268h[2:0]). The default clock frequency is 1 MHz. At this clock rate, it takes approximately 48  $\mu$ s per DWORD during Configuration register initialization. For faster loading of large serial EEPROMs that support a faster clock, the first Configuration register load from the serial EEPROM could be to the **Serial EEPROM Clock Frequency** register.

## 6.6 PCI Express Configuration, Control, and Status Registers

The PCI Express Configuration, Control, and Status registers that can be initialized are detailed in:

- [Chapter 14, “Transparent Port Registers”](#)
- [Chapter 16, “NT Port Virtual Interface Registers – NT Mode Only”](#)
- [Chapter 17, “NT Port Link Interface Registers – NT Mode Only”](#)
- [Chapter 18, “DMA Interface Registers – DMA Mode Only”](#)

## 6.7 Serial EEPROM Registers

The Serial EEPROM register (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offsets 260h through 26Ch) parameters defined in [Section 14.14.2, “Device-Specific Registers – Physical Layer \(Offsets 200h – 25Ch\)”](#) can be changed, using the serial EEPROM. It is recommended that the first serial EEPROM entry (after the [Debug Control](#) register (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offset 1DCh) entry, if programmed), be used to change the [Serial EEPROM Clock Frequency](#) register (offset 268h) value, to increase the clock frequency, and thereby reduce the time needed for the remainder of the serial EEPROM load. When the NT Port Expansion ROM feature is used, the serial EEPROM clock frequency must be 5 MHz or higher. At the last serial EEPROM entry, the [Serial EEPROM Status and Control](#) register (offset 260h) can be programmed to issue a Write Status (WRSR) command, to enable the Write Protection feature(s) within the serial EEPROM data, if needed.

## 6.8 Serial EEPROM Random Write/Read Access

To access the serial EEPROM, a PCI Express, I<sup>2</sup>C, and/or SMBus Master uses the following registers (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port):

- **Serial EEPROM Status and Control** (offset 260h)
- **Serial EEPROM Buffer** (offset 264h)
- **Serial EEPROM 3<sup>rd</sup> Address Byte** (offset 26Ch)

**Note:** To help streamline the text in the following subsections, the specific Port location/access of each register offset is not repeated – only the offset location is mentioned.

The Master can only access the serial EEPROM on a DWord basis (4 bytes aligned to one DWord address).

### 6.8.1 Writing to Serial EEPROM

To write a DWord to the serial EEPROM:

1. If the 3<sup>rd</sup> Address byte (Address bits [23:16]) is needed (when the **Serial EEPROM Status** register *EepAddrWidth* field bits (offset 260h[23:22]) are both Set), write the value to the **Serial EEPROM 3<sup>rd</sup> Address Byte** field (offset 26Ch[7:0]).
2. Write the 32-bit data into the **Serial EEPROM Buffer** register (offset 264h).
3. Issue a Write Enable instruction to the serial EEPROM (Command = 110b, Set Write Enable Latch), by writing the value 0000\_C000h into the **Serial EEPROM Status and Control** register (offset 260h).
4. Calculate and write the combined Address and Command value to write into the **Serial EEPROM Control** register (offset 260h), by combining the serial EEPROM 3-bit Write Data instruction (value 010b) as the *EepCmd[2:0]* field [15:13], together with the serial EEPROM address. Serial EEPROM Address bits [14:2] must be programmed into the **Serial EEPROM Control** register *EepBlkAddr* field [12:0], and serial EEPROM Address bit 15 must be programmed into the **Serial EEPROM Status** register *EepBlkAddr Upper Bit* bit (*that is*, Set offset 260h[20] if the serial EEPROM address is in the upper 32 KB of any 64-KB address block within the serial EEPROM). The data in the **Serial EEPROM Buffer** register is written to the serial EEPROM when the **Serial EEPROM Status and Control** register is written.
5. The serial EEPROM Write operation is complete when a subsequent read of the **Serial EEPROM Status** register *EepCmdStatus* bit (offset 260h[18]) returns 0. At this time, another serial EEPROM access can be started.

Because each PEX 8609 Port and Register address value (REGADDR; refer to [Section 6.5](#)), and its corresponding data value (REGDATA), require 6 bytes of serial EEPROM memory, and the PEX 8609 serial EEPROM interface accesses 4 bytes at a time, two serial EEPROM Writes may be needed to store each set of REGADDR (one word) and REGDATA (1 Dword) entries into the serial EEPROM. To avoid overwriting a word of another set of 6-byte REGADDR and REGDATA values, one of the two Serial EEPROM Writes might need to be a Read-Modify-Write type of operation (preserving one word read from the serial EEPROM, and writing the value back along with a new word value).

## 6.8.2 Reading from Serial EEPROM

*To read a DWord from the serial EEPROM:*

1. If the 3<sup>rd</sup> Address byte (Address bits [23:16]) is needed (when the **Serial EEPROM Status** register *EepAddrWidth* field bits (offset 260h[23:22]) are both Set), write the value to the **Serial EEPROM 3<sup>rd</sup> Address Byte** register *Serial EEPROM 3<sup>rd</sup> Address Byte* field (offset 26Ch[7:0]).
2. Calculate the combined Address and Command value to write into the **Serial EEPROM Control** register (offset 260h), by combining the serial EEPROM 3-bit Read Data instruction (value 011b) as the *EepCmd[2:0]* field [15:13], together with the serial EEPROM address. Serial EEPROM Address bits [14:2] must be programmed into the **Serial EEPROM Control** register *EepBlkAddr* field [12:0], and serial EEPROM Address bit 15 must be programmed into the **Serial EEPROM Status** register *EepBlkAddr Upper Bit* bit (*that is*, Set offset 260h[20] if the serial EEPROM address is in the upper 32 KB of any 64-KB address block within the serial EEPROM).
3. Poll the **Serial EEPROM Status** register until the *EepCmdStatus* bit (offset 260h[18]) is Cleared, which signals that the transaction is complete.
4. Read the four bytes of serial EEPROM data from the **Serial EEPROM Buffer** register (offset 264h).

*For example*, to read the first DWord in the serial EEPROM, write the value 0000\_6000h to Port 0, register offset 260h, and then read Port 0, register offset 264h.

## 6.8.3 Programming a Blank Serial EEPROM

The PEX 8609 supports 1-, 2-, or 3-byte serial EEPROM addressing. 8-Kbit to 512-Kbit SPI EEPROMs use 2-byte addressing. The PEX 8609 requires that the first byte in the serial EEPROM must be the value 5Ah (ASCII Z), as a Validation Signature.

The 2<sup>nd</sup> and 3<sup>rd</sup> bytes contain the quantity of bytes within the serial EEPROM image, beginning with the first register entry at serial EEPROM address 04h. If this Byte Count value exceeds the actual quantity of register entries times 6 (*such as* if the first DWord is programmed to the value 5A00\_FFFFh), the system could hang. To simplify programming of a blank EEPROM (*such as* in a typical production build), the serial EEPROM could be pre-programmed with the first DWord, program to 0000\_005Ah.

A 2-byte address serial EEPROM that is blank (or corrupted) can be programmed according to the following procedure (when the PEX 8609 is in 1-Byte Address mode).

*To program a blank serial EEPROM:*

1. Write the value 0000\_005Ah into the **Serial EEPROM Buffer** register at address [upstream Port BAR0 + 264h].
2. Issue a Write Enable instruction (Command = 110b, Set Write Enable Latch, and enable 2-byte addressing, by writing the value 00A0\_C000h into the **Serial EEPROM Status and Control** register (offset 260h).
3. Copy this data value to serial EEPROM location 0, by writing the value 00A0\_4000h into the **Serial EEPROM Status and Control** register. At this point, the first four bytes in the serial EEPROM now contain the value 0000\_005Ah.
4. Reboot the system, to reset the PEX 8609 so that it re-detects the serial EEPROM.

## 6.9 Serial EEPROM Loading of NT Port Link Interface Registers – NT Mode Only

The **Debug Control** register *Load Only EEPROM NT-Link on Hot Reset* and *Inhibit EEPROM NT-Link Load on Hot Reset* bits (NT Port Virtual Interface if Port 0 is a Legacy NT Port, offset 1DCh[31:30], respectively) control whether the serial EEPROM is to load registers following a Soft Reset (Hot Reset or DL\_Down) to the upstream Port or NT Port Link Interface, as defined in Table 6-3.

**Table 6-3. Serial EEPROM Loading of NT Port Link Interface Registers (Offset 1DCh[31:30] Values)**

| Bit 31 Value | Bit 30 Value | Action                                                                                   |
|--------------|--------------|------------------------------------------------------------------------------------------|
| 0            | 0            | Load all registers from the serial EEPROM.                                               |
| 0            | 1            | Load all registers, except the NT Port Link Interface registers, from the serial EEPROM. |
| 1            | 0            | Load only NT Port Link Interface registers from the serial EEPROM.                       |
| 1            | 1            | Disable serial EEPROM loading of all registers.                                          |

## 6.10 NT Port Expansion ROM – NT Mode Only

The PEX 8609 NT Port Virtual and Link Interfaces support Expansion ROM, as defined in the *PCI r3.0*. Expansion ROM can be implemented for either Port, but not both concurrently. The Expansion ROM image is stored in the serial EEPROM, and its size can be either 16 KB (default, bit is Cleared) or 32 KB (maximum), based upon the **Serial EEPROM Clock Frequency** register *Expansion ROM Size* bit (NT Port Virtual Interface if Port 0 is a Legacy NT Port, offset 268h[16]) value. When the Expansion ROM feature is used, the serial EEPROM clock frequency must be 5 MHz or higher.

By default, the Expansion ROM is enabled on the NT Port Link Interface; however, it can be enabled instead for the NT Port Virtual Interface, by Setting the **Ingress Control** register *Expansion ROM Virtual Side* bit (NT Port Virtual Interface if Port 0 is a Legacy NT Port, offset 660h[23]). The **Expansion ROM Base Address** register (BAR) must be enabled, by Setting the register's *Expansion ROM Enable* bit, in either the NT Port Virtual Interface (offset 30h[0]) or NT Port Link Interface (offset 30h[0]).

The Expansion ROM's location in the serial EEPROM is programmed in the **Serial EEPROM 3<sup>rd</sup> Address Byte** register *Expansion ROM Base Address* field (NT Port Virtual Interface if Port 0 is a Legacy NT Port, offset 26Ch[31:16]), of which the lower six bits, [21:16], map to serial EEPROM byte Address bits [15:10] (aligned to a 256-DWord (1-KB) boundary). The Expansion ROM must not straddle a 64-KB boundary within the serial EEPROM.

The default serial EEPROM Base Address value is as follows:

- **16-KB Expansion ROM (*Expansion ROM Size* bit is Cleared)** – The value is 0020h, which corresponds to serial EEPROM Byte address 2000h (8 KB). The serial EEPROM size must be at least 32 KB.
- **32-KB Expansion ROM (*Expansion ROM Size* bit is Set)** – The value is 0040h, which corresponds to serial EEPROM byte address 4000h (16 KB). The serial EEPROM size must be at least 64 KB.

## Chapter 7 I<sup>2</sup>C/SMBus Slave Interface Operation

### 7.1 Introduction

This chapter discusses the [I<sup>2</sup>C Slave Interface](#) and [SMBus Slave Interface](#).

### 7.2 I<sup>2</sup>C Slave Interface

#### 7.2.1 I<sup>2</sup>C Support Overview

**Note:** This section applies to the I<sup>2</sup>C Slave interface, which uses the [I2C\\_ADDR\[2:0\]](#), [I2C\\_SCL0](#), and [I2C\\_SDA0](#) signals for PEX 8609 register access by an I<sup>2</sup>C Master. The [I2C\\_SCL1](#) and [I2C\\_SDA1](#) signals form the PEX 8609 I<sup>2</sup>C Master interface, which is used only for Serial Hot Plug operation. (Refer to [Chapter 12, “Hot Plug Support.”](#))

Inter-Integrated Circuit (I<sup>2</sup>C) is a bus used to connect Integrated Circuits (ICs). Multiple ICs can be connected to an I<sup>2</sup>C Bus, and I<sup>2</sup>C devices that have I<sup>2</sup>C mastering capability can initiate a Data transfer. I<sup>2</sup>C is used for Data transfers between ICs at relatively low rates (100 Kbps), and is used in a variety of applications. For further details regarding I<sup>2</sup>C Buses, refer to the [I2C Bus, v2.1](#).

The PEX 8609 is an I<sup>2</sup>C Slave. Slave operations allow the PEX 8609 Configuration registers to be read from or written to by an I<sup>2</sup>C Master, external from the device. I<sup>2</sup>C is a sideband mechanism that allows the device Configuration registers to be programmed, read from, or written to, independent of the PCI Express upstream Link.

With I<sup>2</sup>C, users have the option of accessing all PEX 8609 registers through the I<sup>2</sup>C Slave interface. I<sup>2</sup>C provides an alternative to using a serial EEPROM. I<sup>2</sup>C can also be used for debugging, such as if the PEX 8609 upstream Port fails to linkup.

Accordingly, it is recommended that both I<sup>2</sup>C/SMBus access, and the serial EEPROM (or at least its footprint), be included in designs.

The I2C\_SCL0 and I2C\_SDA0 signals can be brought out to a 2x2 pin header on the board, to allow PLX software (*for example*, running on a laptop computer) to access the PEX 8609 registers, using an Aardvark USB-I<sup>2</sup>C adapter connected to this header. (Refer to the *PEX 8609 RDK Hardware Reference Manual* for the header pin design.)

Figure 7-1 provides a block diagram that illustrates how standard devices connect to the I<sup>2</sup>C Bus.

**Figure 7-1. Standard Devices to I<sup>2</sup>C Bus Connection Block Diagram**

## 7.2.2 I<sup>2</sup>C Addressing – Slave Mode Access

To access the PEX 8609 Configuration registers through the I<sup>2</sup>C Slave interface, the PEX 8609 I<sup>2</sup>C Slave address must be configured.

The PEX 8609 supports a 7-bit I<sup>2</sup>C Slave address. The 7-bit I<sup>2</sup>C Address bits can be configured by the serial EEPROM (recommended, if the default address must be changed), or by a Memory Write, in the **I<sup>2</sup>C Configuration** register (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offset 294h, default value 38h), with the lower three bits of the address derived from the I2C\_ADDR[2:0] inputs. Bits [6:0] correspond to Address Byte bits [7:1], with bit 0 of the byte indicating a Write (0) or Read (1).

The I2C\_ADDR[2:0] inputs can be pulled or tied High or Low, to select a different Slave address. Up to eight PEX 8609 devices can share the same I<sup>2</sup>C Bus segment without conflict, provided that each PEX 8609 has its I2C\_ADDR[2:0] inputs strapped to a unique state. More than eight PEX 8609 devices can share the I<sup>2</sup>C Bus, however, if the upper Address bits are programmed in the serial EEPROM.

## 7.2.3 I<sup>2</sup>C Slave Interface Register

The **I<sup>2</sup>C Slave Interface** register, **I<sup>2</sup>C Configuration**, is described in [Section 14.14.5, “Device-Specific Registers – I<sup>2</sup>C Slave Interface \(Offsets 290h – 2C4h\).”](#) The default I<sup>2</sup>C Slave address can be changed in the **I<sup>2</sup>C Configuration** register to a different value, using the serial EEPROM or a Memory Write.

**The I<sup>2</sup>C Slave address must not be changed by an I<sup>2</sup>C Write command.** (Refer to [Section 7.2.2.](#))

Other I<sup>2</sup>C Slave interface registers exist; however, they are for **Factory Test Only**.

## 7.2.4 I<sup>2</sup>C Command Format

An I<sup>2</sup>C transfer starts as a packet with Address Phase bytes, followed by four Command Phase bytes, and one or more Data Phase bytes. The I<sup>2</sup>C packet Address Phase Byte format is illustrated in [Figure 7-2a](#). The Command Phase portion must include 4 bytes of data that contain the following:

- I<sup>2</sup>C Transfer type (Read/Write)
- PCI Express Configuration Register address
- PEX 8609 Port Number being accessed
- Byte Enable(s) of the register data being accessed

When the I<sup>2</sup>C Master is writing to the PEX 8609, the I<sup>2</sup>C Master must transmit the Data bytes to be written to that register within the same packet that contains the Command bytes. [Table 7-2](#) describes each I<sup>2</sup>C Command byte for Write access. [Figure 7-2b](#) illustrates the Command phase portion of an I<sup>2</sup>C Write packet.

When the I<sup>2</sup>C Master is reading from the PEX 8609, the I<sup>2</sup>C Master must separately transmit a Command Phase packet and Data Phase packet. [Table 7-6](#) describes each I<sup>2</sup>C Command byte for Read access. [Figure 7-4b](#) illustrates the Command phase portion of an I<sup>2</sup>C Read packet.

Each I<sup>2</sup>C packet must contain 4 bytes of data. Pad unused packet Data bytes with zeros (0) to meet this requirement.

## 7.2.5 I<sup>2</sup>C Register Write Access

The PEX 8609 Configuration registers can be read from and written to, based upon I<sup>2</sup>C register Read and Write operations, respectively. An I<sup>2</sup>C Write packet consists of Address Phase bytes and Command Phase bytes, followed by one to four additional I<sup>2</sup>C Data bytes. [Table 7-1](#) defines mapping of the I<sup>2</sup>C Data bytes to the Configuration register Data bytes. [Figure 7-2c](#) illustrates the I<sup>2</sup>C Data byte format.

The I<sup>2</sup>C packet starts with the *S* (START condition) bit. Data bytes are separated by the *A* (Acknowledge Control Packet (ACK)) or *N* (Negative Acknowledge (NAK)) bit. The packet ends with the *P* (STOP condition) bit.

If the Master generates an invalid command, the targeted PEX 8609 register is not modified.

The PEX 8609 considers the 1<sup>st</sup> Data byte of the 4-byte Data phase, following the four Command bytes in the Command phase, as register Byte 3 (bits [31:24]). The next three Data bytes access register Bytes 2 through 0, respectively. Four Data bytes are required, regardless of the Byte Enable Settings in the Command phase. The Master can then generate either a STOP condition (to finish the transfer) or a repeated START condition (to start a new transfer). If the I<sup>2</sup>C Master sends more than the four Data bytes (violating PEX 8609 protocol), the PEX 8609 returns a NAK for the extra Data byte(s). (For further details regarding I<sup>2</sup>C protocol, refer to the [I2C Bus, v2.1](#).)

[Table 7-2](#) describes each I<sup>2</sup>C Command byte for Write access. In the packet described in [Figure 7-2](#), Command Bytes 0 through 3 for Writes follow the format specified in [Table 7-2](#).

**Table 7-1. I<sup>2</sup>C Register Write Access**

| I <sup>2</sup> C Data Byte Order | PCI Express Configuration Register Bytes |
|----------------------------------|------------------------------------------|
| 0                                | Written to register Byte 3               |
| 1                                | Written to register Byte 2               |
| 2                                | Written to register Byte 1               |
| 3                                | Written to register Byte 0               |

**Table 7-2. I<sup>2</sup>C Command Format for Write Access**

| Byte                | Bit(s)                                                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |     |             |   |                                                       |   |                                                        |   |                                                         |   |                                                         |
|---------------------|---------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|-------------|---|-------------------------------------------------------|---|--------------------------------------------------------|---|---------------------------------------------------------|---|---------------------------------------------------------|

### 7.2.5.1 I<sup>2</sup>C Register Write

The following tables illustrate a sample I<sup>2</sup>C packet for writing the PEX 8609 **MSI Upper Address** register (offset **50h**) for Port 4, with data 1234\_5678h.

**Note:** The PEX 8609 has a default I<sup>2</sup>C Slave address [6:0] value of **38h**, with the **I2C\_ADDR[2:0]** inputs having a value of 000. The byte sequence on the I<sup>2</sup>C Bus, as listed in the following tables, occurs after the START and before the STOP bits, by which the I<sup>2</sup>C Master frames the transfer.

**Table 7-3. I<sup>2</sup>C Register Write Access Example – 1<sup>st</sup> Cycle**

| Phase   | Value | Description                                                                                          |
|---------|-------|------------------------------------------------------------------------------------------------------|
| Address | 70h   | <b>Bits [7:1] for PEX 8609 I<sup>2</sup>C Slave Address (38h)</b><br>Last bit (bit 0) for Write = 0. |

## 7.2.6 I<sup>2</sup>C Register Read Access

When the I<sup>2</sup>C Master attempts to read a PEX 8609 register, two packets are transmitted. The 1<sup>st</sup> packet consists of Address and Command Phase bytes to the Slave. The 2<sup>nd</sup> packet consists of Address and Data Phase bytes.

According to the [I2C Bus, v2.1](#), a Read cycle is triggered when the Read/Write bit (bit 0) of the 1<sup>st</sup> cycle is Set. The Command phase reads the requested register content into the internal buffer. When the I<sup>2</sup>C Read access occurs, the internal buffer value is transferred on to the I<sup>2</sup>C Bus, starting from Byte 3 (bits [31:24]), followed by the subsequent bytes, with Byte 0 (bits [7:0]) being transferred last. If the I<sup>2</sup>C Master requests more than four bytes, the PEX 8609 re-transmits the same byte sequence, starting from Byte 3 of the internal buffer.

The 1<sup>st</sup> and 2<sup>nd</sup> I<sup>2</sup>C Read packets (illustrated in [Figure 7-4](#) and [Figure 7-5](#), respectively) perform the following functions:

- **1<sup>st</sup> packet** – Selects the register to read
- **2<sup>nd</sup> packet** – Reads the register (sample 2<sup>nd</sup> packet provided is for a 7-bit PEX 8609 I<sup>2</sup>C Slave address)

Although two packets are shown for the I<sup>2</sup>C Read, the I<sup>2</sup>C Master can merge the two packets together into a single packet, by not generating the STOP at the end of the first packet (Master does not relinquish the bus) and generating REPEAT START.

[Table 7-6](#) describes each I<sup>2</sup>C Command byte for Read access. In the packet described in [Figure 7-4](#), Command Bytes 0 through 3 for Reads follow the format specified in [Table 7-6](#).

**Table 7-6. I<sup>2</sup>C Command Format for Read Access**

| Byte                | Bit(s)                                                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |     |             |   |                                                       |   |                                                        |   |                                                         |   |                                                         |

### 7.2.6.1 I<sup>2</sup>C Register Read Address Phase and Command Packet

The following is a sample I<sup>2</sup>C packet for reading the PEX 8609 **Serial EEPROM Buffer** register (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offset 264h) for Port 4, assuming the register value is ABCD\_EF01h.

**Note:** The PEX 8609 has a default I<sup>2</sup>C Slave address [6:0] value of 38h, with the I2C\_ADDR[2:0] inputs having a value of 000. The byte sequence on the I<sup>2</sup>C Bus, as listed in the following tables, occurs after the START and before the STOP bits, by which the I<sup>2</sup>C Master frames the transfer.

**Table 7-7. I<sup>2</sup>C Register Read Access Example – 1<sup>st</sup> Packet**

| Phase   | Value | Description                                                                                          |

### 7.2.6.2 I<sup>2</sup>C Register Read Data Packet

**Note:** The PEX 8609 has a default I<sup>2</sup>C Slave address [6:0] value of **38h**, with the **I2C\_ADDR[2:0]** inputs having a value of 000. The byte sequence on the I<sup>2</sup>C Bus, as listed in the following tables, occurs after the START and before the STOP bits, by which the I<sup>2</sup>C Master frames the transfer.

**Table 7-9. I<sup>2</sup>C Register Read Access Example – 1<sup>st</sup> Cycle**

| Phase   | Value | Description                                                                                         |
|---------|-------|-----------------------------------------------------------------------------------------------------|
| Address | 71h   | <b>Bits [7:1] for PEX 8609 I<sup>2</sup>C Slave Address (38h)</b><br>Last bit (bit 0) for Read = 1. |
| Read    | ABh   | <b>Byte 3 of Register Read</b>                                                                      |
|         | CDh   | <b>Byte 2 of Register Read</b>                                                                      |
|         | EFh   | <b>Byte 1 of Register Read</b>                                                                      |
|         | 01h   | <b>Byte 0 of Register Read</b>                                                                      |

## 7.3 SMBus Slave Interface

### 7.3.1 SMBus Features

- Compliant to the *SMBus v2.0*
- Supports the SMBus Slave function only
- PEX 8609 internal registers can be read and written, through the SMBus Slave interface
- Supports Address Resolution Protocol (ARP-capable)
- Strapping inputs, serial EEPROM, software, or ARP Set the Slave address
- Supports Block Read, Block Write, and Block Read - Block Write Process Call commands to access the registers
- Supports Packet Error Checking
- 10 to 100 KHz Bus operation frequency range

### 7.3.2 SMBus Operation

Based upon I<sup>2</sup>C's principles of operation, SMBus is a two-wire bus used for communication between IC components and the remainder of the system. Electrically, I<sup>2</sup>C and SMBus devices are compatible, and both protocol devices can co-exist on the same bus. Multiple devices, both Masters and Slaves, can be connected to an SMBus segment. PCI Express cards have two optional SMBus pins defined on the connector – SMCLK and SMDAT.

The PEX 8609 implements an *SMBus v2.0*-compliant Slave device, and is used to read and write PEX 8609 registers, through SMBus commands. The PEX 8609 SMBus uses the same SDA data and SCL clock balls that are used for I<sup>2</sup>C, and the I2C\_ADDR[1:0] inputs, to define address assignment (I2C\_ADDR2 is not used as an Address bit in SMBus mode). At any time, either the I<sup>2</sup>C or SMBus feature is enabled, dependent upon the **SMBus Configuration** register *SMBus Enable* bit (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offset 344h[0]) state, which is latched (at Fundamental Reset) to the inverse value of the *STRAP\_SMBUS\_EN#* input. Software can toggle this bit to switch between I<sup>2</sup>C and SMBus functionality.

The PEX 8609 SMBus Slave interface supports three command protocols for register access:

- Block Write
- Block Read
- Block Read - Block Write Process Call

The PEX 8609 SMBus logic also supports the commands that are required to support ARP. ARP is a feature specific to *SMBus v2.0*, through which an SMBus ARP Master can dynamically assign a unique address to each of the SMBus Targets residing on the same bus. Although ARP is an optional feature of the *SMBus v2.0*, PCI and PCI Express cards are required to support ARP. The ARP feature is enabled when the **SMBus Configuration** register *ARP Disable* bit (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offset 344h[8]) is Cleared; this bit is initially latched (at Fundamental Reset) to the value of the I2C\_ADDR2 input.

If ARP is disabled, by I2C\_ADDR2 input being pulled or tied High, the SMBus Slave Address bits [6:2] default to value 001\_10b. Address bits [1:0] are initially latched (at Fundamental Reset) to the I2C\_ADDR[1:0] input values, which allow a maximum of four SMBus-enabled PEX 8609s to co-exist on the same SMBus segment. Software can change the SMBus Slave address, by programming the **SMBus Configuration** register *SMBus Device Address* field (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offset 344h[7:1]).

The PEX 8609 also supports Packet Error Checking and Packet Error Code (PEC) generation, as explained in the *SMBus v2.0*. The *SMBus v2.0* optional feature, *Notify ARP Master* (which requires Master capability on the SMBus) is **not** supported.

### 7.3.3 SMBus Commands Supported

For register access, the SMBus logic supports three commands:

- Block Write (command BEh) is used to write the registers
- Block Write (command BAh), followed by Block Read (command BDh), can be used to read the registers
- Block Read - Block Write Process Call (commands BAh, CDh) can also be used to read registers

SMBus Commands that are not supported by the PEX 8609 (Quick Command, Send Byte, Receive Byte, Write Byte, Write Word, Read Byte, Read Word, and Process Call), are NACKed.

### 7.3.3.1 SMBus Block Write

The Block Write command is used to write to the PEX 8609 registers. General SMBus Block Writes are illustrated in [Figure 7-8](#) and [Figure 7-9](#). The sequence of Bytes include the following, in the sequence listed:

- 7-bit address,
- Command Code that indicates it is Block Write,
- *Byte Count* field with a value of 8h that indicates 4 bytes to set up the register to write (Port Number, register address, Command Byte Enable, and so forth), followed by
- 4 bytes of data to be written into the register

[Figure 7-10](#) explains the elements used in [Figure 7-8](#) and [Figure 7-9](#), and [Figure 7-11](#) indicates the Data Bytes written.

**Figure 7-8. SMBus Block Write Command Format, to Write to a PEX 8609 Register without PEC**

**Figure 7-9. SMBus Block Write Command Format, to Write to a PEX 8609 Register with PEC**

**Figure 7-10. SMBus Packet Protocol Diagram Element Key**

- S -> START condition  
P -> STOP condition
- A -> Acknowledge (this bit position may be 0 for an ACK or 1 for a NACK)
-  -> Master to Slave  
 -> Slave to Master

**Figure 7-11. SMBus Block Write Bytes, as Written to Register**

| 31:24       | 23:16       | 15:8        | 7:0         |
|-------------|-------------|-------------|-------------|
| Data Byte 1 | Data Byte 2 | Data Byte 3 | Data Byte 4 |

**Note:** In each byte, the Most Significant Byte (MSB) is transmitted first.

[Table 7-10](#) provides a description of bytes for an SMBus Block Configuration Space register (CSR) Write.

Block Write transactions that are received with incorrect byte Settings are NACKed, starting from the wrong byte Setting, and including subsequent bytes in the packet. *For example*, if the Byte Count value is not 8, the PEX 8609 NACKs the byte corresponding to the Byte Count value, as well as any Data bytes following within the same packet.

The byte after Data Byte 4, if present, is taken as the PEC byte, and if present, the PEC is checked. If a packet fails Packet Error Checking, the PEX 8609 drops the packet (ignores the Write), and returns NACK for the PEC byte, to the SMBus Master. Packet Error Checking can be disabled, by Setting the **SMBus Configuration** register *PEC Check Disable* bit (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offset [344h](#)[9]). The Byte Count value, by definition, does not include the PEC byte.

**Table 7-10. Bytes for Block CSR Write on SMBus**

| Field (Byte) On Bus | Bit(s)                                                  | Value/Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |     |             |   |                                                       |   |                                                        |   |                                                         |   |                                                         |

| Command Byte 4      | 7:0                                                     | <b>PEX 8609 Register Address [9:2]</b><br><b>Note:</b> All register addresses are DWord-aligned. Therefore, Address bits [1:0] are implicitly Cleared, and then internally incremented for successive I <sup>2</sup> C byte Writes.                                                                                                                                                                                                                                                                                                                                                             |     |             |   |                                                       |   |                                                        |   |                                                         |   |                                                         |

**Sample Register Write Byte Sequence Using SMBus Block Write**

An SMBus Block Write packet to write to the **MSI Upper Address** [63:32] register (offset **50h**) in Port 3, is listed in [Table 7-11](#). The register value is 1234\_5678h, with all Bytes enabled, and without PEC. The default SMBus Device Address is 001\_100b.

**Table 7-11. Sample SMBus Block Write Byte Sequence**

| Byte Number | Byte Type      | Value | Description                                                                                                                                                         |
|-------------|----------------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1           | Address        | 70h   | Bits [7:1] for the PEX 8609 default Slave address of 38h, with bit 0 Cleared to indicate a Write.                                                                   |
| 2           | Command Code   | BEh   | Command Code for register Write, using a Block Write.                                                                                                               |
| 3           | Byte Count     | 08h   | Byte Count. Four Command Bytes and Four Data Bytes.                                                                                                                 |
| 4           | Command Byte 1 | 03h   | For Write command.                                                                                                                                                  |
| 5           | Command Byte 2 | 01h   | Bits [2:0] – Port Selector [3:1].                                                                                                                                   |
| 6           | Command Byte 3 | BCh   | Bit 7 is Port Selector LSB.<br>Bit 6 is <b>reserved</b> .<br>Bits [5:2] are the four Byte Enables; all are active.<br>Bits [1:0] are register Address bits [11:10]. |
| 7           | Command Byte 4 | 14h   | PEX 8609 Register Address bits [9:2] (for offset <b>50h</b> ).                                                                                                      |

### 7.3.3.2 SMBus Block Read

A Block Read command is used to read PEX 8609 registers. Similar to register Reads using I<sup>2</sup>C, an SMBus Write sequence must first be performed to select the register to read, followed by an SMBus Read of the corresponding register. There are two ways a PEX 8609 register can be read:

- Use a Block Write, followed by a Block Read. The Block Write sets up the parameters including Port Number, register address and Byte Enables, and the Block Read performs the actual Read operation.
- Use a Block Read - Block Write Process Call. This command is defined by the *SMBus v2.0*, and performs a Block Write and Block Read, using a single command. The Block Write portion of the message sets up the register to be read, and then a repeated START followed by the Block Read portion of the message returns the register data specified by the Block Write.

**Note:** There is no STOP condition before the repeated START condition.

#### Register Read Using SMBus Block Write, Followed by SMBus Block Read

A general SMBus Block Write and Block Read sequence is illustrated in [Figure 7-12](#).

[Table 7-12](#) describes the Byte definitions for a Block Write bus protocol, to prepare for a subsequent Block Read of the PEX 8609 register.

The PEX 8609 always NACKs any incorrect command sequences, starting with the wrong Byte. Upon receiving the Block Read command, the PEX 8609 returns a PEC to the Master if, after the 4<sup>th</sup> byte of register data, the Master still requests one more Byte. As a Slave, the PEX 8609 recognizes the end of the Master's Read cycle, by observing the Master's NACK response for the last Data Byte transmitted by the PEX 8609.

Incorrect command sequences are always NACKed, starting with the byte that is incorrect. (Refer to [Table 7-13](#).) On the Block Read command, a PEC is returned to the Master, if after the 4<sup>th</sup> byte of CSR data, the return Master still requests for one additional byte. As a Slave, the PEX 8609 will know the end of the Master Read cycle, by observing the NACK for the last byte read from the Master.

Therefore, Address bits [1:0] are implicitly Cleared, and then internally incremented for successive I <sup>2</sup> C byte Writes.                                                                                                                                                                                                                                                                                                                                                             |     |             |   |                                                       |   |                                                        |   |                                                         |   |                                                         |

**Table 7-13. Command Format for SMBus Block Read**

| Field (Byte) On Bus | Bit(s) | Value/Description                                 |
|---------------------|--------|---------------------------------------------------|
| Cmd Code            | 7:0    | CDh, for Block Read (Process Call Rea <b>D</b> ). |

**Sample CSR Read Byte Sequence, Using SMBus Block Write Followed by SMBus Block Read**

An SMBus sequence to write and read the **MSI Upper Address** [63:32] register (offset **50h**) in Port 3, is listed in [Table 7-14](#) and [Table 7-15](#), respectively. The register value is ABCD\_EF01h, and without PEC. The Block Write sets up the Port Numbers, Register address and Byte Enables, and the Block Read performs the real Read operation. The default SMBus Device Address is 001\_100b.

**Table 7-14. SMBus Block Write Portion**

| Byte Number | Byte Type                | Value | Description                                                                                                                                                         |
|-------------|--------------------------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1           | Address                  | 70h   | Bits [7:1] value for the PEX 8609 Slave address of 38h, with bit 0 Cleared to indicate a Write.                                                                     |
| 2           | Block Write Command Code | BAh   | Command Code for register Read setup, using a Block Write.                                                                                                          |
| 3           | Byte Count               | 04h   | Byte Count. Four Command Bytes.                                                                                                                                     |
| 4           | Command Byte 1           | 04h   | Write command.                                                                                                                                                      |
| 5           | Command Byte 2           | 01h   | Bit 3 = 0, <b>Port Selector [3:0]</b> = <i>Port Selector</i> bits (2 <sup>nd</sup> Command byte, bits [3:0] and 3 <sup>rd</sup> Command byte, bit 7).               |
| 6           | Command Byte 3           | BCh   | Bit 7 is Port Selector LSB.<br>Bit 6 is <b>reserved</b> .<br>Bits [5:2] are the four Byte Enables; all are active.<br>Bits [1:0] are register Address bits [11:10]. |
| 7           | Command Byte 4           | 9Dh   | PEX 8609 Register Address bits [9:2] (for offset <b>50h</b> ).                                                                                                      |

**Table 7-15. SMBus Block Read Portion**

| Byte Number | Byte Type               | Value | Description                                                                                     |
|-------------|-------------------------|-------|-------------------------------------------------------------------------------------------------|
| 1           | Address                 | 70h   | Bits [7:1] value for the PEX 8609 Slave address of 38h, with bit 0 Cleared to indicate a Write. |
| 2           | Block Read Command Code | BDh   | Command code for Block Read of PEX 8609 registers.                                              |

**Table 7-16. SMBus Read Command following Repeat START from Master**

| Byte Number | Byte Type | Value | Description                                                                                |
|-------------|-----------|-------|--------------------------------------------------------------------------------------------|
| 1           | Address   | 71h   | Bits [7:1] value for the PEX 8609 Slave address of 38h, with bit 0 Set to indicate a Read. |

**Table 7-17. PEX 8609 SMBus Return Bytes**

| Byte Number | Byte Type   | Value | Description             |
|-------------|-------------|-------|-------------------------|
| 1           | Byte Count  | 04h   | Four Bytes in register. |
| 2           | Data Byte 1 | ABh   | Register data MSB.      |
| 3           | Data Byte 2 | CDh   | Register data [23:16].  |
| 4           | Data Byte 3 | EFh   | Register data [15:8].   |
| 5           | Data Byte 4 | 01h   | Register data LSB.      |

### 7.3.3.3 CSR Read, Using SMBus Block Read - Block Write Process Call

A general SMBus Block Read - Block Write Process Call sequence is illustrated in [Figure 7-13](#). Alternatively, a general SMBus Block Read - Block Write Process Call with PEC sequence is illustrated in [Figure 7-14](#).

Using this command, the register to be read can be set up and read back with one SMBus cycle (a transaction with a START and ending in STOP). There is no STOP condition before the repeated START condition. The command format for the Block Write part of this command has the same sequence as in [Table 7-14](#), except that the Command Code changes to CDh, as illustrated below. Other Bytes remain the same as used in the sequence for SMBus Block Write followed by Block Read.

[Table 7-18](#) lists the Command format for Block Read.

**Figure 7-13. CSR Read Operation Using SMBus Block Read - Block Write Process Call**

**Figure 7-14. CSR Read Operation Using SMBus Block Read - Block Write Process Call with PEC**

**Table 7-18. Command Code for SMBus Block Read**

| Field (Byte) On Bus | Bit(s) | Value/Description                        |
|---------------------|--------|------------------------------------------|
| Cmd Code            | 7:0    | CDh, for Block Read (Process Call ReaD). |

### 7.3.4 SMBus Address Resolution Protocol

Address Resolution Protocol (ARP) is a protocol by which SMBus devices that implement an assignable Slave address feature are enumerated and dynamically assigned non-conflicting Slave addresses, rather than using a fixed Slave address. Although optional in the *SMBus v2.0*, it is mandatory per the *PCI r3.0* for add-in boards, to support ARP. This feature avoids conflicts with addresses used by other devices on a motherboard. ARP also allows multiple devices of the same type to co-exist on the same bus segment, without address conflicts.

To support this feature, a Slave device must implement a unique 128-bit ID, called *Unique Device Identifier (UDID)*. The fields of this ID are provided in [Figure 7-15](#). All ARP commands use the default Device Address, 1100\_001b. There are also two flags that the SMBus devices must implement to support the ARP process:

- **Address Resolved flag (AR)** – A flag bit or device internal state that indicates whether the ARP Master has resolved the device's Slave address
- **Address Valid flag (AV)** – A flag bit or device internal state that indicates whether the device's Slave address is valid

The process of assigning a Slave address starts with the ARP Master issuing a Reset Device or Prepare to ARP command, using the default Device Address. This Clears the AR flag in the Slave device (both flags are Cleared by a Reset Device command). The Master then issues a general Get UDID command. This causes all devices that support ARP to start driving their UDID onto the serial bus. A Target that loses the SMBus arbitration, backs off. Arbitration loss means that a device keeps the SMDAT line floating and it detects 0 driven by another device on the bus. Slave devices that lose arbitration issue NACK in response to further Bytes transmitted on the bus. After the ARP Master finishes the Get UDID sequence, it issues a Set Address command to the Slave device, using the Slave's UDID. All Slave devices on the bus monitor the UDID that is transmitted by the ARP Master, but only the particular device that has the matching UDID adopts the new Slave address, and Sets its own AV and AR flags. After the Slave device sets its AR flag, that device no longer responds to a general Get UDID command, which allows other devices to participate in the ARP process. All ARP commands require PEC checking and generation.

### 7.3.4.1 SMBus UDID

The 128-bit UDID is comprised of the following fields, as illustrated in [Figure 7-15](#) (not to scale). Each UDID field and its default value implemented in the PEX 8609 and meaning are explained in the tables that follow.

**Figure 7-15. 128-Bit SMBus UDID**

| 8 bits            | 8 bits           | 16 bits   | 16 bits   | 16 bits   | 16 bits             | 16 bits             | 32 bits            |
|-------------------|------------------|-----------|-----------|-----------|---------------------|---------------------|--------------------|
| 127:120           | 119:112          | 111:96    | 95:80     | 79:64     | 63:48               | 47:32               | 31:0               |
| Device Capability | Version/Revision | Vendor ID | Device ID | Interface | Subsystem Vendor ID | Subsystem Device ID | Vendor-Specific ID |

**Table 7-19. SMBus Device Capability [127:120]**

| Field | Name            | Default Value | Description                                                                                                                                                                                                 |
|-------|-----------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0     | PEC Supported   | 1             | By default, PEC generation and checking are enabled.                                                                                                                                                        |
| 5:1   | <i>Reserved</i> | 00_000b       |                                                                                                                                                                                                             |
| 7:6   | Address Type    | 10b           | Defaults to 10b. The PEX 8609 SMBus Address Type is implemented as Dynamic and volatile.<br>00b = Fixed address<br>01b = Dynamic and persistent<br>10b = Dynamic and volatile<br>11b = Random number device |

| Field | Name               | Default Value                                                                                                                                                                                    | Description                                                                                                                                                                                                                                                                                                                                                                                      |
|-------|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0  | Vendor-Specific ID | <p>Depends upon I2C_ADDR[1:0] input levels. The four combinations provide the following ID values:</p> <p>00b = 7000_0000h<br/> 01b = B000_0000h<br/> 10b = D000_0000h<br/> 11b = E000_0000h</p> | <p>The Vendor-Specific ID is used to provide a unique ID for functionally equivalent devices. This is for devices that would otherwise return identical UDIDs for the purpose of dynamic address assignment.</p> <p>The combination of two Address bits produces four unique Vendor-Specific ID values, for a maximum of four SMBus-enabled PEX 8609s to co-exist on the same SMBus segment.</p> |

### 7.3.4.2 SMBus Supported ARP Commands

The PEX 8609 supports all ARP Slave commands. The Notify ARP Master command, which requires Master functionality, is **not** supported. [Table 7-27](#) explains the PEX 8609 response to each received ARP command.

**Table 7-27. SMBus Supported ARP Commands, Format, and Actions**

| ARP Command                      | SMBus Command Format                                   | Slave Address                                | Command Code                      | Action                                                                                                                                                                                         |
|----------------------------------|--------------------------------------------------------|----------------------------------------------|-----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### 7.3.5 SMBus PEC Handling

The PEX 8609 supports the optional SMBus v2.0 PEC generation and checking feature. This feature is required for the ARP process; however, it is optional for standard data transfer operation. The PEX 8609 supports PEC Cyclic Redundancy Check (CRC) generation and checking during ARP, as well as during Read/Write transfers to the PEX 8609 registers. The CRC polynomial used for PEC calculation is:

$$C(x) = x^8 + x^2 + x + 1$$

An 8-bit parallel CRC is implemented. The PEC calculation does not include ACK, NACK, START, STOP, nor repeated START bits. An SMBus Master can determine whether a Slave device supports PEC, from the UDID value returned by the Slave device, in response to a Get UDID command.

As a Slave device, the PEX 8609 checks the PEC, if the Master transmits the additional PEC byte and the PEX 8609 PEC checking feature is enabled (default). PEC checking can be disabled, by Setting the **SMBus Configuration** register *PEC Check Disable* bit (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offset 344h[9]).

Additionally, when PEC is enabled, packets received with an incorrect PEC value are dropped. If PEC checking is disabled and a received PEC byte value is incorrect, the PEX 8609 accepts the packet. During a register Read, if the Master requests the additional PEC byte, the PEX 8609 generates and transmits the PEC byte after the register data.

### 7.3.6 Addressing PEX 8609 SMBus Slave

By default, the PEX 8609 supports ARP when the I2C\_ADDR2 input is tied Low, and expects the ARP Master to Set the PEX 8609 SMBus Device Address. If ARP is disabled by I2C\_ADDR2 input being pulled High, the default Slave address is 38h (Address bits [7:1] are 0111\_000b, with Address bit [1:0] values loaded from the I2C\_ADDR[1:0] inputs). The two Address bits allow a maximum of four PEX 8609 SMBus Slaves to co-exist without address conflict on the SMBus, using SMBus Address byte values of 70h, 72h, 74h, and 78h. The I2C\_ADDR[2:0] inputs are loaded immediately after Fundamental Reset, and any subsequent change of input value does not affect functionality.

If the **SMBus Configuration** register *UDID Address Type* field is programmed as Fixed Address (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offset 344h[13:12], are both Cleared) without disabling ARP, the PEX 8609 still participates in ARP, but does not Set the Device Address after ARP successfully completes.

The SMBus Slave Address can be changed at any time, by using software to write to the register's *SMBus Device Address* field (offset 344h[7:1]). ARP can also be enabled or disabled at runtime, by writing to the register's *ARP Disable* bit (offset 344h[8]). If ARP is disabled by software after initially being enabled, the default address (70h) is not used for subsequent transactions. In this case, software must program a Slave address into the *SMBus Device Address* field. When software writes the Device Address, it must also Set the register's *AR Flag* and *AV Flag* bits (offset 344h[11:10], respectively), to indicate that the address is valid and resolved.

Whenever software changes the register's *AV Flag*, *ARP Disable*, and/or *SMBus Device Address* values, software must also Set the register's *SMBus Parameter Reload* bit (offset 344h[15]). Writes to this register bit take effect only when the register's *SMBus Command In-Progress* bit (offset 344h[28]) is Cleared, which indicates that the PEX 8609 SMBus interface is in the Idle state.

### 7.3.7 SMBus Timeout

Unlike I<sup>2</sup>C, where the Slave or Master can indefinitely hold the [I2C\\_SCL0](#) line Low, SMBus has a timeout condition. No device is allowed to hold the I2C\_SCL0 line Low for more than 25 ms. When the PEX 8609, as a Slave-Transmitter, detects that it has pulled the I2C\_SCL0 line Low for more than 25 ms, the PEX 8609 releases I2C\_SCL0, and the logic returns to its default state and waits for another START condition. This can also occur when the Master pulls the I2C\_SCL0 line Low for more than 25 ms during any single Clock Low interval within a transfer in progress, or during the ACK phase, if the Master pulls the I2C\_SCL0 line Low to process a task. Generally, the PEX 8609 pulls the I2C\_SCL0 line Low if SMBus access to registers is delayed by internal arbitration for register access.

## 7.4 Switching between SMBus and I<sup>2</sup>C Bus Protocols

The PEX 8609's I<sup>2</sup>C implementation allows switching between the SMBus and I<sup>2</sup>C protocols, by toggling the [SMBus Configuration](#) register *SMBus Enable* bit (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offset [344h\[0\]](#)).

When operating in SMBus mode, Clearing this bit, using the SMBus Block Write protocol, enables I<sup>2</sup>C protocol for subsequent register accesses. This SMBus Block Write can be transmitted from an SMBus or I<sup>2</sup>C Master, provided that the Block Write Byte sequence conforms to the sequence explained in [Section 7.3.3.1](#). In I<sup>2</sup>C mode, writing 1 to the *SMBus Enable* bit turns On the SMBus protocol, immediately after the Write operation is complete.

## Chapter 8 Virtual Channels and Port Arbitration

### 8.1 Quality of Service Support

Quality of Service (QoS) is a feature offered by PCI Express that was not available before in PCI. QoS refers to being able to guarantee preferential treatment for a particular application or for traffic coming from a particular source. The PEX 8609 provides two methods for acquiring QoS:

- Virtual Channel support
- Port arbitration

### 8.2 Virtual Channel Support

The PEX 8609 supports up to two Virtual Channels (VCs) that act as two completely independent paths through the switch, as defined in the *PCI Express Base r2.0*. Although the two VCs of a Port share the same physical wire/Links, the PEX 8609 has separate queues and separate credit mechanisms for each VC. At the egress stage of each Port, the PEX 8609 has three arbitration methods for determining which TLP from which VC to send on the wire/Link.

The elements of these features are described in the following subsections.

#### 8.2.1 Traffic Class to Virtual Channel Mapping

The Traffic Class to Virtual Channel (TC/VC) mapping is Port-specific and must be configured and enabled for each Port. The default configuration for a PEX 8609 Port maps all TC[7:0] bits to VC0, as defined in the Port's **VC0 Resource Control** register *TC/VC0 Map* bits (offset 15Ch[7:1, 0]). Any of the TC IDs (except TC0) can be mapped to the second VC (*that is*, VC1), by removing them from the *TC/VC0 Map* bits and adding them to the Port's **VC1 Resource Control** register *TC/VC1 Map* field for TC[7:1] (offset 168h[7:1]). If any TCs are mapped to VC1, in addition to performing all steps outlined in [Section 8.4](#) (to set up PCI Express credits for VC1), VC1 must be enabled (**VC1 Resource Control** register *VC1 Enable* bit (offset 168h[31]) is Set).

**Note:** *The actual VC ID of the second VC is Set by the VC1 Resource Control register VC1 ID field (offset 168h[26:24]).*

#### 8.2.2 Ingress VC Arbitration

The PEX 8609 supports hardware-fixed Round-Robin arbitration on the ingress Ports. Round-Robin servicing is performed between the two VCs, per Port. If any ingress Ports are targeting a congested Egress queue (Egress queue depth is greater than its programmable threshold), that ingress Port removes itself from the arbitration pool.

#### 8.2.3 Egress VC Arbitration

The PEX 8609 supports three methods of arbitration on the egress Ports:

- [Fixed-Priority VC Arbitration](#)
- [Round-Robin VC Arbitration](#)
- [Weighted Round Robin Arbitration](#)

Each method is described in the sections that follow.

### 8.2.3.1 Fixed-Priority VC Arbitration

The *PCI Express Base r2.0* defines the default Hardware-Fixed Strict Priority scheme based upon the inherent priority of the VC IDs, where VC1 has higher priority than VC0. The VC IDs alone determine the sequence in which transactions are sent. For this Arbitration scheme, the **Port VC Capability 1** register *Low-Priority Extended VC Counter* field (offset 14Ch[6:4]) must be Cleared.

### 8.2.3.2 Round-Robin VC Arbitration

If the **Port VC Capability 1** register *Low-Priority Extended VC Counter* field (offset 14Ch[6:4]) is programmed to 001b (default), VC0 and VC1 share the same Low-Priority Virtual Channel group. As a result, the PEX 8609 alternates selecting VC0 and VC1 in a fair, Round-Robin manner.

### 8.2.3.3 Weighted Round Robin Arbitration

The PEX 8609 also supports a Weighted Round-Robin (WRR) Arbitration scheme between the two VCs, as defined by the upstream Port's **VC WRR x** registers (Upstream Port, offsets 530h through 538h). Each Port has an 8-way time-slice [7:0], whose Setting determines which of the VCs take that time slot. (Refer to [Section 14.16.1, “Device-Specific Registers – Virtual Channel Weighted Round Robin Arbitration \(Offsets 530h – 540h\).”](#))

## 8.3 Queue Handling

The PEX 8609 implements queues at the ingress and egress Ports. There is arbitration capability for both Ingress and Egress queues. By default, the PEX 8609 attempts to send every packet on the Ingress queue to the Egress queue, until the Egress buffer fills. That results in optimum use of the PEX 8609 on chip buffering; however, it might create a situation in which one high-priority Port takes too much latency.

The packets within each Port's Egress queue are serviced on a first-in, first-out basis within each VC and Type (without violating Conventional PCI Ordering rules). The amount of queuing in the egress side is programmable, per VC. The **Port Egress TLP Threshold** register (offset F10h) establishes a range (minimum and maximum) for the Egress queue depth, for each VC. By reducing the thresholds, the Egress queue size is constrained. A smaller Egress queue means that newly arriving packets from a high-priority source do not have to wait as long for any earlier arriving packets from another source in the same VC, because the quantity of earlier arriving packets is reduced.

Each Port's Egress queue size is programmable, using the **Port Egress TLP Threshold** register fields. The *Port Upper TLP Counter* field (offset F10h[26:16]) allow for a maximum queuing of TLPs in the egress Port. If that maximum is crossed, the destination backpressures any source attempting to write to the destination queue. After the programmed minimum (established by the *Port Lower TLP Counter* field (offset F10h[10:0]) is crossed, the backpressure releases and the source can once again forward TLPs to that destination.

## 8.4 VC1 Ingress Credit

TLPs consume PCI Express credits (and RAM space) upon entering the PEX 8609. When the TLPs are sent out of the PEX 8609 and an ACK is received, these credits (and Buffer space) are released. When a TLP enters the PEX 8609 and the internal credit engine has free credits available, an UpdateFC DLLP is generated, to replenish the credits used by the Transmitter. If there are no credits available, the credit engine waits until an ACK is received from a sent TLP before generating an UpdateFC DLLP.

Refer to [Section 14.16.13, “Device-Specific Registers – Ingress Credit Handler Threshold \(Offsets A00h – B7Ch\),”](#) for the default PCI Express credits of various Ports, based upon their Link widths.

### 8.4.1 VC1

A key element of enabling and using VC1 on a Port/Link is providing for PCI Express credits associated with the VC1 queues.

*To enable, and program the credits for, VC1:*

1. The PEX 8609 VC1 Global Enable defaults to a value of 1 (VC1 support is disabled) at reset.

To enable the VC1 capability, Clear the **Miscellaneous Control** register *VC1 (2nd VC) Disable* bit (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offset 28Ch[0]).

This enables the PEX 8609 to support a second VC, but does not actually enable the VC.

2. Program the VC1 Credit Threshold registers, starting at offset A0Ch. (Refer to [Section 14.16.13, “Device-Specific Registers – Ingress Credit Handler Threshold \(Offsets A00h – B7Ch\).”](#))
3. Set the **VC1 Resource Control** register *VC1 Enable* bit (offset 168h[31]).

VC1 is now enabled.

#### 8.4.1.1 VC1 Threshold Registers

The default values of Credit fields in the various VC1 Credit Threshold registers (in the offset A0Ch through AECh range) are zero (0), which equates to infinite credits. Because the PEX 8609 cannot support infinite credits, except for Non-Posted Payloads, it is **very** important that the Threshold registers are re-programmed before enabling VC1. The minimum value is 1 Header credit and 1 Payload credit or 1 MPS Payload credits (The Posted and Completion Payload minimum is 1 MPS. The Non-Posted Payload credit minimum is 1). Depending upon the Port configuration and MPS, it is possible that even using the minimum VC1 credits, more credits will be advertised than are actually available in the PEX 8609. If this is the case, the Credit Threshold registers for VC0 will also need to be re-programmed, to a smaller value, to compensate for the credits assigned to VC1.

**Note:** *Enabling VC1 and programming the VC1 Credit Threshold registers can have a direct effect on the PEX 8609 and system performance. Because of this possible side effect and the possibility of advertising too many credits, contact PLX Technology Technical Support for assistance, as seen needed, when using VC1.*

### 8.4.1.2 Programming the VC1 Global Enable and Threshold Registers

The Global Enable (offset 28Ch[0]) and Threshold (offsets A0Ch to A2Ch) registers can be programmed in three ways, using:

- Serial EEPROM
- I<sup>2</sup>C
- CPU (software)

If the serial EEPROM is used to Set the Global Enable bit and the VC1 Threshold Registers, nothing further is needed. However, if I<sup>2</sup>C and/or the CPU is used, a Hot Reset to the PEX 8609's upstream Port must be generated after the PEX 8609 Credit Threshold registers are programmed. The Hot Reset is required, to allow the internal Credit Engine to account for the new credits assigned to VC1.

### 8.4.1.3 Usage Example

The simplest example is if only Non-Posted TLPs, or Posted TLPs with a small Payload length, are used. In the example that follows, each Port and type is given two Headers. If one Header is preferred, it is necessary to re-program the appropriate **INCH Threshold VC1** register *UpdateFC High-Priority Threshold for Header Credit* fields.

Example configuration:

- MPS = 128 bytes
- Upstream Port = Port 0
- Downstream Port 1 needs VC1

Registers to write:

1. Program offset A0Ch (Port 0, Posted) to 408h.
2. Program offset A10h (Port 0, Non-Posted) to 401h.
3. Program offset A14h (Port 0, Completion) to 408h.
4. Program offset A24h (Port 1, Posted) to 408h.
5. Program offset A28h (Port 1, Posted) to 401h.
6. Program offset A2Ch (Port 1, Completions) to 408h.
7. Clear offset 28Ch[0], to enable support for VC1.

Following a Fundamental or Hot Reset, a value of 1 is written to the Port 0 and Port 1 **VC1 Resource Control** register *VC1 Enable* bit (offset 168h[31]).

THIS PAGE INTENTIONALLY LEFT BLANK.

## Chapter 9 Performance Features

### 9.1 Introduction

This chapter discusses guidelines for programming on-chip registers, to boost performance beyond that provided by the general-purpose default values, specifically:

- [DLLP Policies](#)
- [Ingress Resources](#)
- [Latency](#)
- [Queuing Options](#)
- [Read Pacing](#)
- [Dual Cast](#)

## 9.2 DLLP Policies

DLLP rates can vary from 0 to 2 or more DLLPs/TLP. The PEX 8609 allows programming to affect the DLLP rate. An increase in DLLPs reduces the total TLP throughput. Therefore, for designs that require high performance, it would be beneficial to minimize DLLP rates. Transmitting fewer DLLPs, however, can result in credit starvation or Replay buffer overflow, which can have a detrimental effect on TLP bandwidth. Care must be taken when changing the default PEX 8609 DLLP transmission rate.

Typically, TLPs have higher transmission priority on the wire than DLLPs. The PEX 8609, however, allows DLLPs to have higher priority under certain conditions, meaning that DLLPs can transmit before starting a new TLP. The decision to transmit a DLLP ahead of a TLP is referred to as *DLLP policy*.

The PEX 8609 can be programmed to alter its default DLLP policies, to emphasize improved TLP throughput, faster acknowledgement, more credit, or simplest behavior. The PEX 8609 default policies are designed to achieve optimal performance for most applications. Programmable choices for a DLLP policy, however, allow for further optimization.

### 9.2.1 ACK DLLP Policy

An *ACK DLLP* is a response indicating to the TLP Transmitter that the Receiver received a “good” copy of the TLP, meaning that it acknowledged receipt of the TLP. The simplest policy is to send 1 Acknowledge Control Packet (ACK) for every received TLP, resulting in a 1 DLLP/TLP rate for ACK alone. What an ACK means to the TLP Transmitter is that the TLP Transmitter can remove any stored copy of that TLP, because it is unnecessary to resend the TLP. ACK DLLPs can be combined, so that one ACK DLLP can serve to acknowledge multiple TLPs. This collapsing of ACKs is the basis of the ACK DLLP policy choices. Less-frequent, more-collapsed ACKs have the least impact on TLP transmit bandwidth, meaning that less-frequent ACKs result in less than 1 DLLP/TLP.

The PEX 8609 ACK policy consists of two parts – a Timer and TLP Counter. The default ACK Timer policy/value varies according to the negotiated Link width, operating Link speed, and Maximum Packet Size, as recommended in the *PCI Express Base r1.1* or *PCI Express Base r2.0*. The values provided in [Table 9-1](#) define some of the possible default values, in symbol times.

**Note:** The values listed in [Table 9-1](#) have been adjusted to be different than the *PCI Express Base r2.0* values, to compensate for hardware-specific latencies.

**Table 9-1. Sample PEX 8609 ACK Latency Timer Values**

| Maximum Payload Size (Bytes) | x4 Gen 2 (Symbol Times) | x2 Gen 2 (Symbol Times) | x1 Gen 2 (Symbol Times) |
|------------------------------|-------------------------|-------------------------|-------------------------|
| 128                          | 124                     | 89                      | 288                     |
| 256                          | 169                     | 134                     | 466                     |
| 512                          | 205                     | 170                     | 610                     |

The ACK Transmission Latency Timer loads the appropriate value when a TLP is received and known to be good, meaning a few clocks after the END framing symbol is received. The Timer counts down each symbol time (every 4 ns (*PCI Express Base r1.1*) or 2 ns (*PCI Express Base r2.0*)). When the Timer reaches 0, an ACK DLLP takes higher priority over new TLPs (*that is*, an ACK DLLP is transmitted before a new TLP is started). The ACK DLLP transmitted acknowledges all TLPs, up to the most recently arrived good TLP.

The TLP Counter counts down on each TLP arrival until it reaches 0, then schedules a high-priority ACK DLLP. The default initialization value for the TLP Counter is 16, meaning a high-priority ACK is scheduled upon the arrival of 16 TLPs. The **Ingress Control Shadow** register *ACK TLP Counter Timeout* field (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offset 664h[10:9]) value controls the Counter, as follows:

- 00b – Allows 16 TLPs before a high-priority ACK (default)
- 01b – Allows 8 TLPs before a high-priority ACK
- 10b – Allows 4 TLPs before a high-priority ACK
- 11b – Disables the Counter

Either the Latency Timer or TLP Counter mechanism can cause a high-priority ACK DLLP to be scheduled, and the first one to do so re-initializes both mechanisms to their starting parameters. *For example*, the time for 16 TLPs can be less than the ACK Timer above, in which case an ACK is sent earlier. The TLP Counter is useful for any system with a large programmed MPS (resulting in a large Timer value), that is capable of sending short TLPs (*such as* 12-byte Memory Reads). Rather than require the Transmitter to save possibly 100+ small TLPs, it need only save 16, plus whatever else arrives during the round-trip time.

If there is no TLP traffic being transmitted (*that is*, the Transmit Link is idle), an ACK DLLP can be transmitted immediately, before the Latency Timer expires. This is an opportunistic, low-priority ACK because it does not contend with a TLP in transmission. When an opportunistic, low-priority ACK is transmitted, both the Latency Timer and TLP Counter re-initialize, waiting for a new TLP to arrive to begin counting again.

The PEX 8609 allows a programmable override of the default Ack\_Latency\_Timer value, on a per-Port basis, by programming the **ACK Transmission Latency Limit** register *ACK Transmission Latency Limit* field (offset 1F8h[11:0]). The value in this register is loaded when a new TLP arrives and a high-priority ACK DLLP is attempted when the Timer reaches 0. For fastest ACK response, this Timer can be programmed to 000h, resulting in one DLLP ACK transmitted immediately per each TLP received. For less impact on Transmit TLP bandwidth, a larger value can be programmed, resulting in less-frequent ACKs.

In general, a slower ACK response does not impact the Receive TLP stream, and aids the TLP Transmit stream. Every PCI Express device contains storage (Retry buffer) for storing TLPs while waiting for ACKs. The amount of Retry buffer storage a device contains is vendor-dependent. The quantity of TLPs the PEX 8609 can store depends upon the type and size of TLPs received. (Refer to [Section 9.3](#).) The PEX 8609 holds TLPs in the Retry buffer while waiting for an ACK. At some point, if the Retry buffer storage fills, no new TLPs can be sent until a new received ACK frees up space. In this case, the ACK can become a performance bottleneck.

## 9.2.2 UpdateFC DLLP Policy

An *UpdateFC DLLP* is transmitted in response to a received TLP. The UpdateFC DLLP replenishes the connected device with additional credit, to allow the Transmitter to transmit more TLPs of that type. Each TLP that arrives consumes credit, and eventually, a stream of TLPs consume all the available credit, unless an UpdateFC DLLP provides additional credit. However, if the connected device has sufficient credit to transmit more TLPs, it is not necessary to transmit UpdateFC DLLPs to it. The UpdateFC policy determines how and when to transmit an UpdateFC DLLP.

There are two parts to the UpdateFC policy – frequency of transmitting the updates and credit amount. This section discusses only the frequency. Refer to [Section 9.3](#) for details regarding credit amounts.

If the PEX 8609 is not transmitting TLPs (*that is*, the Transmit Link is idle), and credit to replenish the credit used becomes available, the PEX 8609 immediately transmits an UpdateFC DLLP to the connected device. This is an opportunistic, low-priority UpdateFC DLLP.

However, if the PEX 8609 is busy transmitting TLPs to the connected device, the PEX 8609 does not transmit an UpdateFC DLLP until a programmed threshold is crossed. The PEX 8609 provides four threshold options – 100%, 75% (default), 50%, and 25%. Whenever the remaining credit drops below the programmed threshold, an UpdateFC DLLP is given high priority, meaning that the UpdateFC DLLP is transmitted before a new TLP is started. There is a separate threshold for Header and Payload credits, for each TLP type – Posted, Non-Posted, and Completion – for each Half-Station Port, located in the **Ingress Credit Handler (INCH) Threshold** registers (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offsets A00h through AECh).

The example of UpdateFC options (provided in [Table 9-2](#)) chart how, for the various options, an UpdateFC is triggered. This example is for a traffic stream of six back-to-back, 256-byte Posted TLPs, using a x4 Port, where the maximum Posted Header credit is 25 and the maximum Posted Payload credit is 128. A 256-byte Payload requires 16 credits (1 credit per 16 bytes). Therefore, each TLP in this case consumes 1 Header and 16 Payload credits.

Once a high-priority UpdateFC is triggered, if there are sufficient on-chip resources to do so, the running credit deficit is fully restored. For most non-congested applications, it is likely that ample chip resources will exist, to fully restore credit with every UpdateFC. However, if resources are running low, only a portion of the running credit is restored. If the threshold for transmitting an UpdateFC remains crossed, then, as more resources become available, a subsequent DLLP is transmitted until the deficit is satisfied.

Selecting the 100% policy results in a high-priority UpdateFC for every TLP received. By itself, this policy results in 1 DLLP/TLP, without factoring in the ACK policy. The 75% policy triggers 1 DLLP for every 2 TLPs for this traffic load, which results in 0.5 DLLP/TLP without the ACK. The 50% policy results in 0.25 DLLP/TLP, and the 25% policy results in 0.16 DLLP/TLP.

**Table 9-2. Example UpdateFC Options**

| <b>TLP Received</b> | <b>Running Credit Header, Payload Consumed/Total</b> | <b>25% Remains<br/>Triggers when 6 Header or 32 Payload Credits Remain</b> | <b>50% Remains<br/>Triggers when 12 Header or 64 Payload Credits Remain</b> | <b>75% Remains<br/>Triggers when 18 Header or 96 Payload Credits Remain</b> | <b>Less than 100% Remains<br/>Update ASAP</b> |
|---------------------|------------------------------------------------------|----------------------------------------------------------------------------|-----------------------------------------------------------------------------|-----------------------------------------------------------------------------|-----------------------------------------------|
| TLP0                | 24/25, 112/128                                       | –                                                                          | –                                                                           | –                                                                           | UpdateFC                                      |
| TLP1                | 23/25, 96/128                                        | –                                                                          | –                                                                           | UpdateFC                                                                    | UpdateFC                                      |
| TLP2                | 22/25, 80/128                                        | –                                                                          | –                                                                           | UpdateFC                                                                    | UpdateFC                                      |
| TLP3                | 21/25, 64/128                                        | –                                                                          | UpdateFC                                                                    | UpdateFC                                                                    | UpdateFC                                      |
| TLP4                | 20/25, 48/128                                        | –                                                                          | UpdateFC                                                                    | UpdateFC                                                                    | UpdateFC                                      |
| TLP5                | 19/25, 32/128                                        | UpdateFC                                                                   | UpdateFC                                                                    | UpdateFC                                                                    | UpdateFC                                      |

### 9.2.3 Unidirectional DLLP Policies

For unidirectional traffic, the PEX 8609 DLLP policies allow the most-frequent DLLPs, because DLLPs do not interfere with TLPs. (DLLPs flow in the opposite direction of TLPs.)

The PEX 8609 can transmit a DLLP ACK almost immediately upon receiving and verifying a TLP. A faster ACK results in fast Transmitter de-allocation of the TLP, and can therefore allow a shallow TLP Replay buffer. The default values can be overwritten, to increase or decrease the ACK DLLP rate. For unidirectional traffic, a small number, *such as 1*, is recommended.

The number programmed into the **ACK Transmission Latency Limit** register *ACK Transmission Latency Limit* field (offset 1F8h[11:0]) Sets the ACK Transmission Latency Timer, to count the quantity of symbol times after receiving a TLP, before transmitting an ACK.

Similar to the ACK programmability, the PEX 8609 can immediately transmit an UpdateFC after receiving only the TLP Header. By transmitting an UpdateFC earlier, the total credit advertised can be minimized. For large Payload sizes (*such as 1,024 and 2,048 bytes*), reserve PEX 8609 resources only as necessary. By programming fewer credits and having a fast UpdateFC policy, the system does not run out of credits and the PEX 8609 does not waste Buffer space on reservations that do not arrive. The following are the recommended Settings:

- Set the UpdateFC policy for unidirectional traffic to 100%
- Set the credits to be sufficient to allow 3 to 4 TLPs

## 9.3 Ingress Resources

**Note:** *This section of the data book introduces the concept of Half Stations (which is sometimes mentioned, but not often, in the other chapters within this data book). Its use is necessary here, however, to “illustrate” their function.*

The PEX 8609 manages ingress credit on an even- and odd-numbered-Port basis; therefore, there are separate Credit Handler engines for the Even and Odd Ports. An internal hardware processing partition of Even or Odd Ports is referred to as a *Half Station*. All even-numbered-Ports belong to Half Station 0. All odd-numbered-Ports belong to Half Station 1.

For each Half Station, there are two central resources of on-chip ingress credit RAM – Header and Payload. The total Half-Station Header RAM size is 256 Header credits. The total Half-Station Payload RAM size is 2,048 Payload credits. A Header credit reserves 4 DWords of RAM storage, regardless of whether the Header size is 3 or 4 DWords. By design, a PEX 8609 Half Station reserves 12 Header credits and 32 Payload credits out of the RAM totals, for special hardware-specific storage needs.

The [STRAP\\_PORTCFG\[1:0\]](#) inputs configure the quantity of enabled Ports, and the Link width of each Port. At initialization, the PEX 8609 optimally assigns the credits, based upon the selected Port configuration.

Header RAM stores TLP Headers, meaning that every Header credit advertised reserves one Header RAM location, and every TLP received on the PEX 8609 uses one Header RAM location. After subtracting the reserved operational Half Station Header RAM locations, there remains a net total of 244 Header entries available.

Payload RAM stores TLP Payload. A Payload credit is in units of 16 bytes. Of the 2,016 user-configurable entries, 4 credits must be allocated for each Posted and Completion Header credit advertised. These credits are used internally, for linking Posted and Completion TLP Payload to their respective Header.

Every Port receives and transmits the following three traffic types (packets):

- Posted (P)
- Non-Posted (NP)
- Completions (Cpl)

Each Port can be assigned to one or two Virtual Channels (VC0 or VC1).

All three traffic types and each Virtual Channel (VC0 and/or VC1) needs credit, for each Port. The **INCH Threshold** register bit fields (refer to [Table 9-6](#)) allocate the credit to be reserved (and advertised) for each Port VC, and traffic type. Once allocated, the credits remain dedicated to each Port, VC, and traffic type.

As TLPs arrive, they are stored on the PEX 8609, until an ACK is received from the final destination. Until the ACK is received, each TLP stored consumes credit, and continues to occupy RAM until released. The RAM/credit is released only after the Receiver has acknowledged to the sender the arrival of the TLP, without any errors per ACK/Negative Acknowledge (NAK) policy. The total quantity of TLPs stored, but not yet forwarded to, and acknowledged by, the next PCI Express device, depends upon congestion and the next PCI Express device’s ACK policy.

There are trade-offs between the quantity of credits allocated for a particular traffic type and Port combination, perhaps more for one system configuration than another. To alleviate these trade-offs, the PEX 8609 contains an innovative Dynamic Buffering design that allows a programmable-sized portion of the RAM to store any of the three traffic-type TLPs from any Half-Station Port. The credits that remain, after allocating credits for each of the three traffic types and VC for each Port, become part of a *Dynamic buffer*. The Dynamic buffer is essentially a common pool of Half-Station credits, and is discussed in detail in [Section 9.3.2](#) and [Section 9.3.3](#).

The PEX 8609 default credit allocation values, which create a variable-sized Dynamic buffer for each of the possible Port configurations, are optimal for most applications. Detailed tables of the default initial credit allocation for all three TLP types, and an explanation of the common credit pool, are addressed in the following sections.

### 9.3.1 Initial Credit Allocation

The PEX 8609 default credit allocation values depend upon the strapped Link width, not the negotiated Link width. The initial credit values that the Initialization Flow Control (InitFC) DLLP advertises on a per-Port basis, which the PEX 8609 transmits after Linkup, are listed in [Table 9-3](#) (in credits) and [Table 9-4](#) (in bytes).

The amount of credit that a Port initially advertises is controlled by the **INCH Threshold** registers (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offsets A00h through AECh). (Refer to [Section 9.3.3](#).) The default value of these registers changes, depending upon the [STRAP\\_PORTCFG\[1:0\]](#) input levels. Because of the way the hardware links the default **INCH Threshold** register credit values into actual reserved RAM storage, in some cases, one or two additional initial Payload credits are allocated out of the Half-Station common pool. If this occurs, the Port advertises this additional initial credit in its InitFC DLLPs.

**Note:** *The default initial credits for VC1 are all infinite. If VC1 is enabled, the user must calculate and program the needed optimal VC1 initial credit values. These values should be programmed into the **INCH Threshold** register fields, using a serial EEPROM.*

**Table 9-3. Initial Port Credit Allocation (*where 1 Header credit means storage is available for one Header of any size, and 1 Payload Credit = 16 bytes*)**

| Configured Port Link Width | Posted Header/Payload | Non-Posted Header/Payload | Completion Header/Payload |
|----------------------------|-----------------------|---------------------------|---------------------------|
| <b>VC0</b>                 |                       |                           |                           |
| x1                         | 7/64                  | 7/infinite                | 5/64                      |
| <b>VC1</b>                 |                       |                           |                           |
| x1                         | infinite/infinite     | infinite/infinite         | infinite/infinite         |

**Table 9-4. Initial Port Credit Allocation for Header/Payload (*where 1 Header credit means that storage is available for one Header, in bytes; Payload credits are listed in bytes*)**

| Configured Port Link Width | Posted Header/Payload | Non-Posted Header/Payload | Completion Header/Payload |
|----------------------------|-----------------------|---------------------------|---------------------------|
| <b>VC0</b>                 |                       |                           |                           |
| x1                         | 112/1,024             | 112/infinite              | 80/64                     |
| <b>VC1</b>                 |                       |                           |                           |
| x1                         | infinite/infinite     | infinite/infinite         | infinite/infinite         |

### 9.3.2 Dynamic Buffering

The PEX 8609 default credit values are optimal for most applications, to maintain back-to-back TLP traffic indefinitely, without running out of credit. After any of the initial credit (storage space) is used, more resources are automatically made available from the Half-Station Dynamic buffer, to maintain the initial credit allotment. These additional resources, taken from the Dynamic buffer, are not pre-reserved. Therefore, they can be used for either Virtual Channel or any of the three TLP types – Posted, Non-Posted, or Completion (P, NP, or Cpl, respectively). Because the TLP type is not pre-specified, these extra resources are termed a *common credit pool*.

When credit is actually replenished depends upon the UpdateFC DLLP policy (refer to [Section 9.2.2](#)), which is controlled by Setting the **INCH Threshold** registers (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offsets A00h through AECh[19:18, 17:16], as appropriate). These thresholds are relative to the initial credits allocated to a Port. Common Pool credits that are allocated to a Port. Common Pool credits that are allocated to a Port before a high-priority UpdateFC DLLP is sent can be de-allocated, if the Port's initial credits are restored before the UpdateFC DLLP is sent.

The common credit pool for Header and Payload credit is as follows:

- **Common Header pool** – What remains in the Header RAM space, after subtracting the advertised Header credits of each Half-Station Port for each of the three TLP types, plus one or two VCs. [Figure 9-1](#) illustrates the way in which the initial allocation of the PEX 8609 Header RAM is partitioned (by default) for a Half-Station x4 Port, with only VC0 in use.
- **Common Payload pool (Common Payload/Completion pool)** – What remains after subtracting the following from the Payload RAM:
  - 4 credits for each Posted and Completion Header Credit advertised, for each Half-Station Port
  - Posted (Payload) credits advertised for each VC and Half-Station Port
  - Completion credits advertised for each VC and Half-Station Port

[Figure 9-2](#) illustrates the way in which the PEX 8609 Payload (and Completion) RAM is partitioned (by default) for one Half-Station x4 Port.

**Figure 9-1. One x4 Port Default Configuration of Header RAM (256 Total Credits)****Figure 9-2. One x4 Port Payload/Completion RAM Default Configuration of 2,048 Credits**

A larger common pool allows the most flexibility for handling any possible instantaneous traffic stream, without backpressuring ingress flows. The PEX 8609's initial credit allocation default Settings leave sufficient on-chip RAM to accommodate numerous large TLPs in the common pool, after default values for the initial credits are subtracted. [Table 9-5](#) summarizes the common pool default allotment for several Half-Station Port configurations.

**Table 9-5. Half-Station Port Configuration Common Pool Default Allotments**

| Half-Station Port Configuration | Common Pool Header Credits | Common Pool Payload Credits |
|---------------------------------|----------------------------|-----------------------------|
| x4                              | 166                        | 1,328                       |
| x1x1x1x1                        | 168                        | 1,312                       |

**Notes:**

1. Actual RAM usage for TLP and Header storage and linking is variable.
2. The subtraction of 4 credits for each Posted and Completion Header credit advertised, for each Port, is a simplification – the Common Pool credit values can be larger.

### 9.3.3 Ingress Credit Handler Threshold Registers (Offsets A00h through AECh)

***Note:** Although the entire end range of the **INCH Threshold** registers is included in the register reference, only those offsets associated with active Ports are used. All others are either **reserved** or **Factory Test Only**, as identified in [Section 14.16.13, “Device-Specific Registers – Ingress Credit Handler Threshold \(Offsets A00h – B7Ch\).”](#)*

For each Port, there are six sets of **INCH Threshold** registers (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offsets A00h through AECh) – Posted, Non-Posted, and Completion – one each, per VC. [Table 9-6](#) lists the lower 16 bits for each register. (To view the complete register set, refer to [Section 14.16.13, “Device-Specific Registers – Ingress Credit Handler Threshold \(Offsets A00h – B7Ch\).”](#))

The Non-Posted credits for Payload are Cleared, which equates to infinite credits. Because Non-Posted TLPs only have a 1-DWord Payload, they will never be longer than 5 DWords. Because the Header RAM is 5 DWords wide, only one Non-Posted Header credit is necessary to store a Non-Posted TLP.

**Table 9-6. INCH Threshold Registers (Offsets A00h through AECh), Payload and Header Credit Fields**

| Ports and VC | Register Offset | Type       | Payload |                 | Header |               |
|--------------|-----------------|------------|---------|-----------------|--------|---------------|
|              |                 |            | Bit(s)  | Description     | Bit(s) | Description   |
| Port 0, VC0  | A00h            | Posted     | 8:3     | Payload Credit  | 15:9   | Header Credit |
|              | A04h            | Non-Posted | 8:0     | 000h (infinite) | 15:9   | Header Credit |
|              | A08h            | Completion | 8:3     | Payload Credit  | 15:9   | Header Credit |
| Port 0, VC1  | A0Ch            | Posted     | 8:3     | Payload Credit  | 15:9   | Header Credit |
|              | A10h            | Non-Posted | 8:0     | 000h (infinite) | 15:9   | Header Credit |
|              | A14h            | Completion | 8:3     | Payload Credit  | 15:9   | Header Credit |
| Port 1, VC0  | A18h            | Posted     | 8:3     | Payload Credit  | 15:9   | Header Credit |
|              | A1Ch            | Non-Posted | 8:0     | 000h (infinite) | 15:9   | Header Credit |
|              | A20h            | Completion | 8:3     | Payload Credit  | 15:9   | Header Credit |
| Port 1, VC1  | A24h            | Posted     | 8:3     | Payload Credit  | 15:9   | Header Credit |
|              | A28h            | Non-Posted | 8:0     | 000h (infinite) | 15:9   | Header Credit |
|              | A2Ch            | Completion | 8:3     | Payload Credit  | 15:9   | Header Credit |
| Port 4, VC0  | A60h            | Posted     | 8:3     | Payload Credit  | 15:9   | Header Credit |
|              | A64h            | Non-Posted | 8:0     | 000h (infinite) | 15:9   | Header Credit |
|              | A68h            | Completion | 8:3     | Payload Credit  | 15:9   | Header Credit |
| Port 4, VC1  | A6Ch            | Posted     | 8:3     | Payload Credit  | 15:9   | Header Credit |
|              | A70h            | Non-Posted | 8:0     | 000h (infinite) | 15:9   | Header Credit |
|              | A74h            | Completion | 8:3     | Payload Credit  | 15:9   | Header Credit |
| Port 5 VC0   | A78h            | Posted     | 8:3     | Payload Credit  | 15:9   | Header Credit |
|              | A7Ch            | Non-Posted | 8:0     | 000h (infinite) | 15:9   | Header Credit |
|              | A80h            | Completion | 8:3     | Payload Credit  | 15:9   | Header Credit |

### 9.3.4 Adjusting Initial Credit Values (Ingress Resources)

The default Initial Credit values listed in [Table 9-3](#) and [Table 9-4](#) can be changed; however, to do so, the values must be changed by serial EEPROM and/or I<sup>2</sup>C, before the initial advertisement. It is also possible to use software to program the Credit registers over the Link; however, if the Link is up, credit cannot be removed, and values can only be increased. The Credit registers are sticky – a Hot Reset preserves any programmed values, and thereby allows any of the available programming methods to program credits at any time, even after the Link is up, if a Hot Reset is issued afterward to re-run the InitFC sequence.

When changing any credit value, follow the rules outlined in this section; otherwise, the credit can be incorrectly issued and data can be lost.

Credit is partitioned/programmed on a Half-Station basis. All even-numbered-Ports belong to Half Station 0. All odd-numbered-Ports belong to Half Station 1. Per the *PCI Express Base r2.0*, the minimum initial credit must be sufficient to meet the credit requirements of the MPS. To meet this requirement with a 2,048-byte MPS, the minimum credit value assigned to a Port, for both Posted and Completion TLPs, must be 128 credits each (one credit represents 16 bytes of storage). The MPS is restricted to 512 bytes when the programmed Link width is x1.

Additionally, because each TLP may not optimally fill each location in the internal RAM, the Header credit affects the Payload credit used to store the Payloads. Therefore, for every Posted or Completion Header credit reserved, 4 credits from the Payload/Completion RAM must also be held in reserve.

The following abbreviations are used in the rules outlined in this section:

- *PH* is the total Posted Header credits that are advertised or can be stored
- *NPH* is the total Non-Posted Header credits that are advertised or can be stored
- *CH* is the total Completion Header credits that are advertised or can be stored
- *MPS* is the Maximum Payload Size
- *Hmax* is the maximum quantity of Header credits that can be assigned, per Half Station
- *Pmax* is the maximum quantity of Payload and Completion credits

The total credit advertised, per Half Station, must follow these rules:

1. Sum of all Header credits  $\leq H_{max} = 244$ .  
Sum of all Header credits = sum (all Ports PH + NPH + CH).
2. Payload and Completion credit must be sufficient for 1 MPS, for each Port.

**Note:** *Non-Posted Payload credit is infinite and Read-Only.*

3. Sum of all Payload and Completion credits assigned, per Half Station,  
is  $\leq P_{max} = 2,016 \leq (\text{Advertised Posted Payload} + \text{Advertised Completion Payload} + (4 \times (\text{sum of all Ports PH} + \text{CH})))$ .

**Programming Example** – To satisfy these rules, the following example is presented, using the default values of a Half Station strapped to have two x4 Ports, for VC0.

1. From [Table 9-3](#), the sum of all VC0 Header credits =  $2 \times (26 + 26 + 26) = 156$ , which is  $\leq H_{\max} = 244$ .
2. For a 2,048-byte MPS, 128 credits must be allocated/advertised for both a Posted and Completion Payload, for each Port. Therefore, for the two Ports in the example, this uses  $2 \times (256 + 224) = 960$  credits, or 1,000 Payload/Completion credits.
3. For this case, the Payload/Completion credits used = 1,000 credits + 4 credits ( $2 \text{ Ports} \times (26 + 26)/\text{Port}$ ) = 1,416 credits which is  $\leq P_{\max} (2,016)$ .

For this example:

- Common Header Pool =  $(244 - 156) = 88$  Header Credits
- Common Payload/Completion Pool =  $(2,016 - 1,416) = 600$  Payload/Completion Credits

### 9.3.5 Credit Allocation When Common Pool Is Consumed

A Half Station's common credit pool is consumed by any Port's Ingress or Egress queue for that Half Station, on a first-come, first-served basis. If the Half Station's common pool is completely consumed (and therefore, each Half-Station Port's credit), the PEX 8609 Half Station is in a congested state. In the congested state, the Half Station is unable to provide additional credit to any of its Ports, until credit is released. Credit is released only after the Receiver acknowledges the packet with an ACK. In this state, the following register fields provide a method for users to weight each Port's Request for more credit, from the Half Station's internal credit allocation logic:

- **INCH Threshold Port x VC0 Posted** register *Congested Port Weight* field (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offsets A00h, A18h, A60h, A78h, A90h, AA8h, AC0h, AD8h[22:20])
- **INCH Threshold Port x VC1 Posted** register *Congested Port Weight* field (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offsets A0Ch, A24h, A6Ch, A84h, A9Ch, AB4h, ACCh, AE4h[22:20])

In the congested state, the Half Station's internal credit allocation logic decides which Port will receive the next available credit, by evaluating the following:

- Each VC and Port's *Congested Port Weight* field Setting
- Quantity of Common Pool credits that the Port has already consumed
- History of which Ports have recently received credit

**Table 9-7**, By default, the *Congested Port Weight* field for each VC and Port is Cleared. The default value is called an *effective rate Setting*. For the default case, if a Half Station is configured into five Ports (x4, x1, x1, x1, x1), each Port receives credit updates based upon on the Port's negotiated Link width. The x4 Port would receive 50% of the credit updates, and the four x1 Ports would each receive effectively 1/8<sup>th</sup> of the remaining credits as they become available.

**Table 9-7** defines the *Congested Port Weight* field values. Requests are weighted, based upon the Port's effective Link width, relative to the effective Link widths of the other Half Station's Ports. Settings can reduce or increase a Port's effective rate, down to x1 or up to x8, respectively. (*That is*, regardless of the actual Link width, a Link can only be reduced to a x1 effective rate, or increased to a x8 effective rate.) The effective Link Width Request weight is calculated, by multiplying the Port's negotiated Link width (not strapped width) by the *Congested Port Weight* field Setting.

The Half Station's internal credit allocation logic decides how to allocate the Common Pool credits, as they become available in a congested scenario. Regardless of the Common Pool credit availability, each Port maintains ownership of the ingress credits that were initially allocated to it. In a congested state, those dedicated credits are replenished to their assigned Port, after an ACK is received from the final destination.

The effective rate Setting applies to both the Common Header and Common Payload/Completion pools, for the selected Half Station, Port, and VC. Although the effective rate Setting is in the **INCH Threshold Port x VC0 Posted** and **INCH Threshold Port x VC1 Posted** registers, the value applies to credit updates for all three possible traffic types (Posted, Non-Posted, and Completion).

**Note:** The offsets for these registers are listed on the previous page.

**Table 9-7. INCH Threshold Port x VC0 Posted and INCH Threshold Port x VC1 Posted Register *Congested Port Weight* fields (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, field [22:20]) Values**

| <b><i>Congested Port Weight Setting</i></b><br><b>(Bits [22:20])</b> | <b>Description</b>                                                                                                                         |
|----------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| 000b = eff_rate                                                      | Request is weighted, based upon the Port's Link width relative to the effective Link widths of the other Half Station's Ports.             |
| 001b = 2x eff_rate                                                   | Increases the weight of a Request by 2 ( <i>for example</i> , a x4 Link Width Request weight increases to a x8 Link Width Request weight). |
| 010b = 4x eff_rate                                                   | Increases the weight of a Request by 4 ( <i>for example</i> , a x1 Link Width Request weight increases to a x4 Link Width Request weight). |
| 011b = 8x eff_rate                                                   | Increases the weight of a Request by 8 ( <i>that is</i> , a x1 Link Width Request weight increases to a x8 Link Width Request weight).     |
| 100b = 0                                                             | Port receives no credit from the common pool, until a decongested state is reached.                                                        |
| 101b = eff_rate/2                                                    | Decreases the weight of a Request by 2 ( <i>for example</i> , a x8 Link Width Request weight decreases to a x4 Link Width Request weight). |
| 110b = eff_rate/4                                                    | Decreases the weight of a Request by 4 ( <i>for example</i> , a x8 Link Width Request weight decreases to a x2 Link Width Request weight). |
| 111b = eff_rate/8                                                    | Decreases the weight of a Request by 8 ( <i>that is</i> , a x8 Link Width Request weight decreases to a x1 Link Width Request weight).     |

### 9.3.6 INCH Port Pool Registers (Offsets 940h through 948h)

The **INCH Port Pool** registers (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port) are registers whose original intent was to provide another level of reservation for Common Pool credits. The registers are named as follows, and are located at:

- **INCH Port Pool for Ports 0, 1**, offset 940h
- **INCH Port Pool for Ports 4, 5, 6, 7**, offset 944h
- **INCH Port Pool for Ports 8, 9**, offset 948h

These registers are essentially redundant to what is accomplished by changing the values of the **INCH Threshold** registers (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offsets A00h through AECh).

**Consider the INCH Port Pool registers to be reserved and only change the credit Settings, using the INCH Threshold registers. Do not change the INCH Port Pool registers from their default values, unless directed otherwise by PLX Technical Support.**

The **INCH Port Pool** registers initial values are provided in sets of two for each Port – Payload pool and Header pool. [Table 9-8](#) lists the bit decode for each Port.

The initial values of the **INCH Port Pool** registers are all Cleared which means that, by default, there is no additional level of reservation. Additionally, the **INCH Threshold** registers default values evenly allocate all available credit, across all enabled Ports.

**Table 9-8. INCH Port Pool Settings (Offsets 940h through 948h)**

| Ports   | Payload Pool Bit(s) <sup>a</sup> | Header Pool Bit(s) <sup>a</sup> |
|---------|----------------------------------|---------------------------------|
| 0, 4, 8 | <a href="#">2:0</a>              | <a href="#">6:4</a>             |
| 1, 5, 9 | <a href="#">10:8</a>             | <a href="#">14:12</a>           |
| 6       | <a href="#">18:16</a>            | <a href="#">22:20</a>           |
| 7       | <a href="#">26:24</a>            | <a href="#">30:28</a>           |

a. The hyperlinks provided to the bits listed are to register offset 940h or 944h.

### 9.3.7 Wait for ACK – Avoiding Congestion

Once a TLP arrives, it remains on the PEX 8609 until it is no longer required. The TLP can quickly egress the PEX 8609. However, until an ACK is received, indicating that the TLP was correctly received, each TLP must remain on the PEX 8609 and be ready to be re-sent multiple times. While on the PEX 8609, the TLP continues to use Half-Station common pool resources.

The *PCI Express Base r2.0* recommends sending an ACK within the approximate time it takes to send 1.5 to 3 MPS TLPs. It does not, however, suggest that smaller TLPs obtain faster ACKs. This data book describes the way in which the PEX 8609 sends an ACK. However, the PEX 8609, has no way of knowing its Link partner's ACK policy.

To minimize the amount of TLPs stored on the PEX 8609 while waiting for an ACK, follow these guidelines:

- Avoid traffic patterns where a great deal of back-to-back TLP bytes travel from a wide Link to a single narrow Link, because the narrow Link can only forward TLPs at a fraction of the ingress rate. *For example*, if a 4-KB MRd is transmitted upstream from a x1 Port and the upstream Port is x4, the upstream Port transmits a 4-KB CPLD to the Requester, four times faster than the Requester can receive the data. If the Requester transmits many of these MRd Requests, large amounts of CPLD data that require storage on the PEX 8609 will quickly accumulate.
- If there are many small TLPs, determine whether the PEX 8609's ACK response time can be reduced, as per the *PCI Express Base r2.0* guidelines.
- Evenly space the TLP pattern, rather than use a burst of many back-to-back TLPs followed by a long stall, to even the distribution and accommodate a fixed ACK Transmission Latency Timer.

# 9.4 Latency

Latency is the length of time it takes to proceed from one event to another. Latency can be measured in several different ways, but perhaps the most common measurement for a switch is *Start TLP-to-Start TLP (STP-to-STP) latency*. Figure 9-3 and Table 9-9 illustrate an STP-to-STP Latency Measurement. When the Egress Start TLP symbol is transmitted out of a switch before the Ingress Port End symbol arrives, the transfer is termed *Cut-Thru*. If an Egress Port queue is not already established, the PEX 8609 always cuts the packet through. The PEX 8609 has the same latency, regardless of whether the traffic is upstream or peer-to-peer.

As expected with the PEX 8609 Cut-Thru architecture, STP-to-STP latency is basically constant for all Payload sizes. A faster Link can receive the Header for decode faster, with a slightly lower latency. There will generally be a constant latency for any ingress width to the same egress width, or any ingress width to a smaller egress width, operating at the same Link speed. This is indicated by the shaded-green entries in Table 9-9.

For cases in which the egress Port has a higher bandwidth than the ingress Port, then a fraction of the packet, given by the following formula:

$$F = (E - I) / E$$

must be buffered (to prevent under-run in the middle of the TLP), before the TLP can be forwarded to the egress Link.

where

- *F* is the fraction sum
- *E* is egress bandwidth
- *I* is ingress bandwidth

Figure 9-3. Start TLP-to-Start TLP Latency Measurement

Table 9-9. Sample STP-to-STP Latency

| Latency for TLP with a Data Payload of 4/64/256 Bytes (in ns) |              |             |             |
|---------------------------------------------------------------|--------------|-------------|-------------|
|                                                               | From Ingress |             |             |
|                                                               | x4 Gen 2     | x2 Gen 2    | x1 Gen 2    |
| To Egress                                                     |              |             |             |
| x4 Gen 2                                                      | 148/154/138  | 164/214/314 | 184/310/614 |
| x2 Gen 2                                                      | 150/150/166  | 174/180/180 | 200/296/488 |
| x1 Gen 2                                                      | 180/180/180  | 188/188/188 | 180/180/188 |

### 9.4.1 Host-Centric Latency

Host-centric traffic flows only to or from the Host. Host-centric latency depends upon the quantity of active streams. If there is only one active stream, or if the total Host bandwidth is greater than or equal to the sum of all traffic streams, the traffic is well-balanced and the latency measurements provided in [Table 9-9](#) apply.

If there is more traffic than an upstream Host can sink, congestion occurs when all the TLPs concurrently attempt to use the limited Host bandwidth. The latencies in that case depend upon the level of traffic congestion. In this case, Host bandwidth is at 100%, but the total downstream bandwidth is more than the Host bandwidth, and latencies continue to increase until the congestion eases.

Another case of increased latency is if the Host serially sends large amounts of Read Completion data to one downstream Port and then another downstream Port. *For example*, if the upstream Port is x4 and the two downstream Ports are both x1, it appears that there should not be a latency build-up, because the bandwidth matches. However, if the Host cannot interleave the destinations, one destination must wait until the Host completes transmitting traffic to the other destination, before it can receive any Read Completion data. In this case, the round-trip Read latency can significantly increase.

*For example*, suppose that one downstream Port transmits 16, 4-KB MRd Requests upstream. Those Read Requests represent 64 KB of data. If the upstream Port is x4 and the downstream Port is x1, the Read Completions back up into the PEX 8609, perhaps all the way to the Root Complex. Suppose another downstream Port transmits only one, 1-KB MRd Request upstream, shortly after the 16, 4-KB MRds were received by the Root Complex. For many Root Complexes, this one, 1-KB Read Request from the second device must wait for the 16, 4-KB MRd Requests from the first device to complete before being serviced. The PEX 8609 buffer is approximately 10 KB; therefore, the second downstream device must wait for (64-10) 54 KB of Completion data to transmit across a x1 Link before it begins to receive its Read Completions. On a x1 Link, 54 KB takes about 48  $\mu$ s, which significantly increases the second device's latency. The PEX 8609 contains Read Pacing logic that prevents this type of latency increase that occurs when multiple devices concurrently read data from the Root Complex. (Refer to [Section 9.6](#).)

## 9.4.2 Peer-to-Peer Latency

If an Egress Port queue is not established (*such as* multiple streams to the same destination Port), peer-to-peer latencies match the best-case values listed in [Table 9-9](#). The PEX 8609 has the same latency, regardless of whether the traffic is Host-centric or peer-to-peer. Latency is constant in the non-congested case, no matter the source Port nor destination Port, if the Source Port has the same or greater bandwidth than the destination Port.

The discussion for Host-centric traffic applies to all Ports for peer-to-peer traffic. It is recommended that there be a method outside the scope of this data book, however, for balancing traffic flow for peer-to-peer applications.

## 9.4.3 Other Latency Measurements

In addition to STP-to-STP latency, there are other latencies to consider. [Table 9-10](#) lists various best-case latencies for several Link widths and speeds. Transmitted DLLPs can be required to wait for a TLP. DLLP policies can prevent sending a DLLP for a time period longer than the best case.

**Table 9-10. Miscellaneous Best Case Link Latencies (in ns)**

| Latency <sup>a</sup>                | x4 Gen 2 | x2 Gen 2 | x1 Gen 2 |
|-------------------------------------|----------|----------|----------|
| STP in to UpdateFC SDP <sup>b</sup> | 132      | 144      | 180      |
| TLP's END in to ACK SDP             | 72       | 72       | 72       |
| UpdateFC SDP in to STP              | 116      | 120      | 140      |

a. Gen 1 latency values are expected to be the same as, or very close to, Gen 2 latency values.

b. SDP is "Start DLLP".

## 9.5 Queuing Options

On-chip queuing does not exist in balanced bandwidth scenarios, where the total ingress bandwidth is less than or equal to the egress bandwidth. In the common case, where the total ingress bandwidth is greater than the egress bandwidth, queues develop on the PEX 8609. The PEX 8609 provides two alternatives, as to where to locate such queuing (refer to [Figure 9-4](#)):

- **Destination queue** – Associated with a single Destination Port. All the TLPs in a Destination queue will egress out the same Port.
- **Source queue** – Associated with a single ingress Port. All the TLPs in a Source queue come from the same Port.

Each queue is discussed in the sections that follow.

**Figure 9-4. On-Chip Queuing**

## 9.5.1 Destination Queuing

**Note:** For the queuing examples provided in this section, “Port 1” indicates “first Port,” not the Port physically identified as Port 1.

The default behavior is for all queues to develop at the Destination Port. If TLPs are arriving from four sources to a common Destination Port, the TLPs are scheduled according to First-In, First-Out (FIFO). The crossbar can forward a TLP every 4 ns, to each Destination queue; therefore, it is unlikely that a Source queue can develop or last very long.

A Destination queue develops whenever the *ingress rate* – the sum of all ingress Ports targeting a Destination Port – exceeds the egress rate. A Destination queue might also develop in a credit-starved situation, where there is no credit available to forward TLPs.

For example, if TLPs arriving from four sources all go to a common Destination Port, the TLPs are scheduled, based upon the order in which they arrive at the Destination queue FIFO<sup>a</sup>. If all four flows are equally active, the TLPs naturally interleave as 1,2,3,4,1,2,3,4. If three of the Ports, however, have a head start before the fourth Port turns On, the output can be 1,2,3,1,2,3,1,2,3,1,2,3,1,2,3,4,1,2,3,4. In this case, all the new Port (Port 4) TLPs must wait for the earlier Port 1,2,3 traffic to be transferred before the Port 4 TLPs can be transferred. Therefore, the latency for Port 4 traffic to travel through the PEX 8609 can widely vary, based upon the traffic passing through the switch.

---

a. Conventional PCI Strong Ordering rules can override the FIFO. Conventional PCI requires Posted TLPs to be able to pass Non-Posted and Completion TLPs, to avoid deadlock.

## 9.5.2 Source Queuing

**Caution:** *Source Queuing and [Read Pacing](#) should not be concurrently enabled. The two features are incompatible and doing so can result in Fatal errors.*

**Note:** *For the queuing examples provided in this section, “Port 1” indicates “first Port,” not the Port physically identified as Port 1.*

Source queuing can be enabled for applications that require deterministic bounded latency for a few Ports, while the latency for other Ports is not as important.

Source queuing limits the Destination queue depth. When the Destination queue reaches the maximum depth, any subsequent TLPs targeting that Port are not forwarded, but are queued up in a per-Source Port-based queue. The Source Port queue does not forward TLPs until the Destination queue drops to a programmed threshold, upon which TLP forwarding is re-enabled.

**Note:** *A Source Port queue that cannot forward to a Destination queue blocks all subsequent TLPs arriving on that same Source Port, although the target Port is a different destination.*

The **Port Egress TLP Threshold** register (offset [F10h](#)) controls the minimum and maximum queue depths. [Table 9-11](#) summarizes the register bit Settings. The Port Lower TLP Counter is the quantity of TLPs that the Destination queue must reach after becoming saturated, before re-enabling TLP forwarding. The Port Upper TLP Counter is the quantity of TLPs that can be queued in the Destination queue.

In the Destination queue example provided in [Section 9.5.1](#), the early arriving Port 1,2,3 TLPs stalled Port 4’s TLP for an indeterminate length of time. By programming, with source queuing enabled and a Destination Port Lower TLP Counter programmed to 1 and Port Upper TLP Counter programmed to 3 (TLPs), the worst case is that Port 4 must wait for three TLPs (1,2,3) before getting its first turn. With these Settings, the example TLP output would be 1,2,3,4,1,2,3,4,1,2,3,4. The *turn to be forwarded* refers to a Port Arbitration wait, described in [Section 9.5.3](#).

To avoid unnecessary idles on the destination Link, program a Port Lower TLP Counter of 1, and a Port Upper TLP Counter of 2.

**Table 9-11. Port Egress TLP Threshold Register Port Lower and Upper TLP Counters (Offset F10h)**

| Bit(s) <sup>a</sup> | Name                          | Description                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------------|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 10:0                | <b>Port Lower TLP Counter</b> | When Source Scheduling is disabled due to the Port Upper TLP Counter (threshold) being exceeded, Source Scheduling is re-enabled when the Port TLP Counter goes below the Port Lower TLP Counter (this threshold). Because the default Setting of this field is 7FFh (2,047), which is greater than the maximum amount of TLPs that can be queued in the PEX 8609, the Source Scheduler is disabled, by default. |
| 26:16               | <b>Port Upper TLP Counter</b> | When the Port TLP Counter is greater than or equal to this value, the Source Scheduler disables TLP Scheduling to this egress Port. Because the default Setting of this field is 7FFh (2,047), which is greater than the maximum amount of TLPs that can be queued in the PEX 8609, the Source Scheduler is disabled, by default.                                                                                |

a. Bits not identified in [Table 9-11](#) are **reserved**.

### 9.5.3 Port Arbitration

In the crossbar that connects the Source queues to the Destination queues, there is a Port Arbiter for each Destination Port. The Port Arbiter ensures that each Source Port receives a deterministic bandwidth connecting to a Destination Port. The Port Arbiter ensures that each Source Port receives a deterministic bandwidth connecting to a Destination Port. Every Port has two default fixed Round-Robin Port Arbiters, one for each VC.

In addition to the default fixed Round-Robin Port Arbiter, there is one Device-Specific Weighted Round-Robin (WRR) Port arbitration hardware resource that can be enabled by system software. The Device-Specific WRR arbitration is also Round-Robin, but with programmable weighting for a particular Port or Ports. When WRR is enabled, the Arbiter is parked on the upstream Port, if the upstream Port is Port 0 through Port 3; if the upstream Port is on a higher-numbered Port, the Arbiter is parked on Port 0.

System software discovers the Port Arbitration Capability, as reflected in the **VC0 Resource Capability** register (offset 158h[1:0]). If the system software needs to make use of an advertised WRR arbitration with 32-phase capability for a Port, it programs the Port's **VC0 Resource Control** register *Port Arbitration Select* field (offset 15Ch[19:17]) to 001b.

The WRR Source Port Arbiter has a 32-phase Port Arbitration Table, as outlined in the *PCI Express Base r2.0*, and documented in the **Port Arbitration Table Phase x** registers (When WRR is enabled, Arbiter is parked on the upstream Port, if the upstream Port is Port 0 through Port 3; if the upstream Port is on a higher-numbered Port, the Arbiter is parked on Port 0, offsets 1A8h through 1B4h). (Refer to the *PCI Express Base r2.0*, as well as [Section 14.13.1, "WRR Port Arbitration Table Registers \(Offsets 1A8h – 1BCh\),"](#) for further details.)

Once one or more Phase registers are written, the software writes the Port's **VC0 Resource Control** register *Load Port Arbitration Table* bit (offset 15Ch[16]). When written, the register values are transferred to the WRR arbitration logic, and immediately take effect.

Port arbitration makes decisions on a per-TLP basis. A Port with more short TLPs will appear to receive less bandwidth, compared to a Port with fewer long TLPs, if both Ports have the same weight and both target a congested Port.

### 9.5.4 Port Bandwidth Allocation

For applications that need to allocate a fixed bandwidth to each Port, the PEX 8609 can help enforce the relative bandwidth ratio between Ports in a congested scenario.

By combining source queuing, Port Arbitration, and initial credit, as well as some knowledge of average Payload size, many combinations of Port bandwidth allocation are possible.

## 9.6 Read Pacing

**Caution:** *Source Queuing and Read Pacing should not be concurrently enabled. The two features are incompatible and doing so can result in Fatal errors.*

The Read Pacing feature is supported on all Ports. The Read Pacing Configuration registers, however, are implemented only on the upstream Port.

PCI Express has a weakness concerning the quantity of outstanding bytes requested by Reads. It is possible that a single device can overwhelm the system with a reasonable quantity of large Read Requests, thereby impacting the performance of other connected devices, by filling the ingress transaction queue in the Root Complex.

The Root Complex must handle the transactions in the order in which they are posted. Transactions posted from less aggressive reading devices, which may be more sensitive to latency, suffer performance reductions due to the unfairly weighted path (head of line blocking) in the transaction queue that the large reads represent.

Read Pacing attempts to apply some rules to Memory Read Requests, so that no one Port can overwhelm a system. There are two aspects to the PEX 8609's Read Pacing capability:

- Read spacing
- Read threshold

The following sections provide examples and further information regarding Read Pacing.

### 9.6.1 Read Pacing Example

Figure 9-5 illustrates an example of a system that benefits from Read Pacing.

**Figure 9-5. Read Pacing Example**

In a typical Host-centric application, endpoints have Direct Memory Access (DMA) engines that write to and read from Main memory. A performance bottleneck can occur during the Read to Main memory, through the Root Complex. For the example illustrated in [Figure 9-5](#), the aggressive endpoint sends many large (16, 4-KB) Memory Read Requests, while another endpoint, or Timid Endpoint (TEP), sends only two 1,500-byte Memory Read Requests. The TEP then waits for a response before sending additional Read Requests<sup>a</sup>.

If either endpoint is running by itself, neither sees a problem. However, if both endpoints are concurrently active, the aggressive endpoint dominates the Root Complex Memory Controller. In addition, due to the bandwidth mismatch, Completions can queue up in the PEX 8609, creating too many Completions for the switch to store at one time. As a result, the PEX 8609 backpressures the Root Complex for Completions. The Root Complex can only forward Completions to the PEX 8609 at the aggressive endpoint's rate, which is significantly less than the Root Complex could otherwise handle.

The net impact is not to the aggressive endpoint, because there are a sufficient quantity of Completions queued up in the PEX 8609 to keep it busy. In fact, the aggressive endpoint experiences better performance with a switch, than connected directly to the Root Complex<sup>b</sup>. Rather, the TEP experiences lower performance results. Its Memory Read Requests wait in line behind multiple aggressive endpoint Requests, and the Root Complex can drain Requests only at the same rate of the PEX 8609, not at the upstream Link's capacity.

[Figure 9-6](#) illustrates how a PCI Express switch, without Read Pacing, forwards Memory Read Requests (MRds).

Read Pacing solves the performance loss seen by the TEP, while improving the aggressive endpoint's performance. The following sections provide examples of the way in which the PEX 8609 functions when Read Pacing is enabled, and Read Spreading is enabled or disabled.

**Figure 9-6. Read Pacing Off (Disabled)**

a. This is based upon an actual setup in a third-party lab. Fibre Channel endpoints can easily send 16, 4-KB MRd at a time, while Gigabit Ethernet endpoints might send only one or two 1,500-byte endpoints at a time.

b. Without a switch, when the Root Complex has something else to do, the aggressive endpoint loses its data stream. With a switch, the buffering of multiple Completions hides the fact that the Root Complex is multitasking.

## 9.6.2 Read Spacing (Spreading) Logic

Read Spacing (also referred to as *Read Spreading*) spreads out Read Requests. The PEX 8609 Read Spacing logic looks at the Read Request size and the endpoint's bandwidth, to determine how often to forward subsequent Read Requests. *For example*, Read Requests arriving on a x1 Link can only sink data at a x1 rate. If a x1 endpoint submits multiple Read Requests to a x4 Link, the Read Spacing logic does not forward the subsequent Read Requests until the endpoint has sufficient time to sink a portion of the Completion data from the previous Read Requests.

Initially, a queue of Completions must build up to hide the time that it takes for the data to return. As a result, Reads are forwarded at 2x the endpoint's bandwidth. This 2x rate is maintained until a threshold of outstanding Read data is reached, at which time Reads are forwarded at 1x the endpoint's bandwidth.

**Read Pacing must be enabled for Read Spreading to be enabled.** That is, for a Port to have Read Spreading enabled, the Port's **Read Pacing Control** register *Port x Read Pacing Disable* and **Read Spreading Control** register *Port x Memory Read Spreading Disable* bits (offsets 544h[9:4, 1:0] and 548h[9:4, 1:0], respectively) must both be Cleared.

Figure 9-7 illustrates the way in which the PEX 8609 forwards Read Requests when the Read Pacing and Read Spreading-related bits are enabled. (Refer to Section 9.6.5 for additional register/bit information.) The PEX 8609 continues to spread and forward the Read Requests, until the amount of Completion data for which it is waiting exceeds the value programmed in the **Read Pacing Threshold x** register(s) for that Link width (Upstream Port, and also the NT Port Virtual Interface if the NT Port is a Legacy NT Port, offsets 54Ch and 550h, respectively).

**Figure 9-7. Read Pacing On (Enabled) and Read Spreading On (Enabled)**

### 9.6.3 Read Threshold

The Read threshold is the maximum quantity of outstanding DWords (1 DWord = 4 bytes) that the endpoint Port requested to be read, but were not yet returned as Completion data. The threshold is related to the PEX 8609's buffering capacity – all outstanding Read data ought to be able to be buffered in the switch, to remain out of the way of other Completions for other endpoint's Read Requests.

After a Port reaches its Read threshold, subsequent Read Requests from that Port queue up in the PEX 8609, waiting for Completion data to reduce the outstanding count to below the threshold. If an overabundant quantity of Read Requests queue in the PEX 8609, no additional Read credit is allocated, which backpressures the Read Requester. [Figure 9-8](#) illustrates the way in which the PEX 8609 forwards Read Requests when its Read Spacing logic is enabled and Read Spreading logic is disabled.

**Figure 9-8. Read Pacing On (Enabled) and Read Spreading Off (Disabled)**

### 9.6.4 Read Pacing Benefits

When Read Pacing logic is enabled, the PEX 8609 provides the follow benefits:

- Maximum Read latency that an endpoint may experience can be dramatically reduced.  
By reducing the amount of queued Read Requests, and therefore pending Read Completion data at the Root Complex, new Read Requests from Ports that do not have pending Read Requests can be serviced with a predictable and/or reasonable amount of latency.
- Timid endpoint bandwidth is dramatically increased in busy applications.  
Because queues of pending Read Requests in the Root Complex are limited, and congestion caused by a large amount of Completion data intended for a high-bandwidth, needy Port (or Ports) is avoided, the bandwidth needs of endpoints with smaller bandwidth requirements are met (*that is*, the endpoints are not starved).
- PEX 8609's Read Pacing Threshold logic allows all busy Ports to be equally serviced in congested scenarios, regardless of their individual Read requesting behavior.

*For example*, all Ports might simultaneously request data, some aggressively and some timidly. While unable to quickly drain their queued Completions, the Ports' Read Pacing Threshold logic forwards the additional Read Requests to the Root Complex, equally and fairly, while ensuring Completion data is available for each Port, when the Port is ready to accept it.

## 9.6.5 Enabling Read Pacing and Read Spreading

**Caution:** *Source Queuing and [Read Pacing](#) should not be concurrently enabled. The two features are incompatible and doing so can result in Fatal errors.*

Read Pacing is disabled, by default. To enable Read Pacing, the Port's [Read Pacing Control](#) register *Port x Read Pacing Disable* bit (Upstream Port, and also the NT Port Virtual Interface if the NT Port is a Legacy NT Port, offset [544h](#)[9:4, 1:0]) must be Cleared. A bit value of 0 enables Read Pacing, whereas a value of 1 (default) disables Read Pacing.

The Port's [Read Spreading Control](#) register *Port x Memory Read Spreading Disable* bit (Upstream Port, and also the NT Port Virtual Interface if the NT Port is a Legacy NT Port, offset [548h](#)[9:4, 1:0]) is used to enable or disable Read Spreading. A value of 1 disables Read Spreading for the corresponding Port. Read Spreading is enabled, by default (value of 0); however, it is overridden by the Port's *Port x Read Pacing Disable* bit, by default.

Both sets of Read Spreading and Pacing Control register bits are represented in [Table 9-12](#). (For complete details, refer to the register offset [54Ch](#) and [550h](#) description provided in [Section 14.16.2](#), “[Device-Specific Registers – Read Pacing \(Offsets 544h – 554h\)](#).”) [Figure 9-6](#) through [Figure 9-8](#) illustrate what occurs when the bits are enabled or disabled.

The Read Pacing thresholds are Set, based upon the Source Port's programmed Link width. The [Read Pacing Threshold 0](#) register controls the threshold values for x4 Link widths, and the [Read Pacing Threshold 1](#) register controls the threshold values for x1 Link widths (Upstream Port, and also the NT Port Virtual Interface if the NT Port is a Legacy NT Port, offsets [54Ch](#) and [550h](#), respectively). The thresholds are in DWords. Narrower Link widths have lower thresholds, because they must buffer smaller quantities.

**Table 9-12. Read Pacing and Memory Read Spreading Control Register Disable Bits**

| Register Offset | Bit(s) <sup>a</sup> | Description                                                                                                                                                                                                                                                                | Default |
|-----------------|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| 544h            | 9:4, 1:0            | <b>Port x Read Pacing Disable</b><br>Bits [9:4, 1:0] correspond to the Read Pacing Disable for Ports 9 through 4, 1, and 0, respectively.<br>0 = Read Pacing is enabled for this Port<br>1 = Read Pacing is disabled for this Port                                         | FFh     |
| 548h            | 9:4, 1:0            | <b>Port x Memory Read Spreading Disable</b><br>Bits [9:4, 1:0] correspond to the Memory Read Spreading Disable for Ports 9 through 4, 1, and 0, respectively.<br>0 = Memory Read Spreading is enabled for this Port<br>1 = Memory Read Spreading is disabled for this Port | 00h     |

a. Bits not identified in [Table 9-12](#) are **Reserved** or **Factory Test Only**.

## 9.7 Dual Cast

### 9.7.1 Introduction

This section describes the functions and programming of the PEX 8609's Dual Cast feature. A typical system configuration and register programming example is also provided.

Dual Cast allows programs to concurrently write the same data to two different destinations. Whenever Posted Memory Write TLPs entering the PEX 8609 through a designated Port (referred to as the *Dual Cast Source Port*) are addressed to designated memory regions (referred to as *Dual Cast BARs*), the switch automatically generates a copy of the original TLP (referred to as the *Dual Cast Copy TLP*), replacing the original TLP's address with one that is mapped to an egress Port designated as the *Dual Cast Destination Port*.

When an incoming TLP is copied in this manner, both the original TLP and Dual Cast copy TLP are concurrently queued at their respective egress Ports, effectively doubling the PEX 8609's egress rate for the same ingress rate.

### 9.7.2 Dual Cast System Model

[Figure 9-9](#) illustrates Dual Cast functions. In this figure, the designated Dual Cast Source Port is Port 0. Only Memory Write TLPs that enter the PEX 8609 through this Port (or alternately, any Port) are subject to Dual Casting. Dual Cast Control registers allow the programmer to define up to eight separate Dual Cast BARs, over which Dual Casting will be applied. If a Memory Write TLP enters the PEX 8609 through the designated Dual Cast Source Port, **and** its Header address falls within an active Dual Cast BAR, then the switch automatically generates a Dual Cast Copy TLP, replacing the original TLP's Header address with a new address mapped to the designated Dual Cast Destination Port.

Dual Cast BARs can be mapped to any egress Port of the PEX 8609. In other words, original Memory Write TLPs that are being copied can exit the PEX 8609 on any egress Port, as they would normally. However, Dual Cast Copy TLPs, regardless of which Dual Cast BAR generates them, must all exit the PEX 8609 through the designated Dual Cast Destination Port.

The Dual Cast Destination Port can also be configured as NT. Refer to [Section 9.7.5](#) for additional programming requirements.

**Figure 9-9. Typical Dual-Cast System Model**

## 9.7.3 Dual Cast Control Registers

This section describes each of the Dual Cast Control registers. Eight sets of identical registers describe each of the eight Dual Cast BARs. An additional register specifies the Dual Cast Source and Destination Ports. These registers are described, in detail, in the following subsections. For a complete listing of the registers, refer to [Section 14.14.10, “Device-Specific Registers – Vendor-Specific Dual Cast Extended Capability \(Offsets 448h – 51Ch\).”](#) The Dual Cast registers are located in Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port.

### 9.7.3.1 Dual Cast Low BAR[0-7], Dual Cast High BAR[0-7]

The 32-bit **Dual Cast Low** and **High BAR<sub>x</sub>** registers in Port 0 (refer to [Table 9-13](#)) are used to define the 64-bit physical Base address of each of the Dual Cast BAR address windows, numbered 0 through 7.

**Dual Cast Low BAR<sub>x</sub>** contains the lower 32-bits of the Base address of Dual Cast BAR window *n*. Only the upper 12 bits [31:20] of this register are used to specify address. Bits [19:0] of this register are not de-coded, and are hardwired with the value 0\_000Ch. Thus, Dual Cast BARs are naturally aligned on 1-MB boundaries. Because the 1-MB boundary is also a 4-KB boundary, any Memory Write TLP that falls within the Dual Cast BAR's Address range will be guaranteed never to exceed the top of the Dual Cast BAR<sub>x</sub> range.

**Dual Cast High BAR<sub>x</sub>** contains the upper 32 bits of the Base address for Dual Cast BAR window *n*. For Base addresses in the lower 4 GB or for all 32-bit systems, this register should be Cleared (default).

**Table 9-13. Dual Cast High/Low BAR<sub>x</sub> Register Locations**

| Base Address Register | Port 0 Register Offset                 |                                         |
|-----------------------|----------------------------------------|-----------------------------------------|
|                       | Dual Cast Low[31:0]<br>(Lower 32 Bits) | Dual Cast High[31:0]<br>(Upper 32 Bits) |
| BAR0                  | 450h                                   | 454h                                    |
| BAR1                  | 468h                                   | 46Ch                                    |
| BAR2                  | 480h                                   | 484h                                    |
| BAR3                  | 498h                                   | 49Ch                                    |
| BAR4                  | 4B0h                                   | 4B4h                                    |
| BAR5                  | 4C8h                                   | 4CCh                                    |
| BAR6                  | 4E0h                                   | 4E4h                                    |
| BAR7                  | 4F8h                                   | 4FCh                                    |

### 9.7.3.2 Dual Cast Low BAR[0-7] Translation, Dual Cast High BAR[0-7] Translation

The 32-bit **Dual Cast Low** and **High BAR<sub>x</sub> Translation** registers in Port 0 (refer to [Table 9-14](#)) specify the destination address of the Dual Cast Copy TLP for their corresponding Dual Cast BARs. When a Dual Cast Copy TLP is formed, the original TLP's Header Address bits are replaced with corresponding Address bits from these registers.

#### Restrictions

- Dual Cast BAR Translation addresses must be mapped to the Dual Cast Destination Port, as specified in the **Dual Cast Source Destination Port** register (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offset [510h](#)). (Refer to [Section 9.7.3.4](#).) While the original TLPs that are copied can be mapped to any PEX 8609 Port, copied TLPs from all Dual Cast BARs must be mapped to the Dual Cast Destination Port.
- Dual Cast BAR Translation address plus the Dual Cast BAR window size must never exceed the Address range mapped to the Dual Cast Destination Port.

**Table 9-14. Dual Cast High/Low BAR<sub>x</sub> Translation Register Locations**

| Base Address Register | Port 0 Register Offset                             |                                                     |
|-----------------------|----------------------------------------------------|-----------------------------------------------------|
|                       | Dual Cast Low Translation[31:0]<br>(Lower 32 Bits) | Dual Cast High Translation[31:0]<br>(Upper 32 Bits) |
| BAR0                  | <a href="#">458h</a>                               | <a href="#">45Ch</a>                                |
| BAR1                  | <a href="#">470h</a>                               | <a href="#">474h</a>                                |
| BAR2                  | <a href="#">488h</a>                               | <a href="#">48Ch</a>                                |
| BAR3                  | <a href="#">4A0h</a>                               | <a href="#">4A4h</a>                                |
| BAR4                  | <a href="#">4B8h</a>                               | <a href="#">4BCh</a>                                |
| BAR5                  | <a href="#">4D0h</a>                               | <a href="#">4D4h</a>                                |
| BAR6                  | <a href="#">4E8h</a>                               | <a href="#">4ECh</a>                                |
| BAR7                  | <a href="#">500h</a>                               | <a href="#">504h</a>                                |

### 9.7.3.3 Dual Cast Low BAR[0-7] Setup, Dual Cast High BAR[0-7] Setup

The 32-bit **Dual Cast Low** and **High BARx Setup** registers in Port 0 (refer to [Table 9-15](#)) form a 64-bit value used to define the Dual Cast BAR window size, which increases in powers of 2 in size, starting from 1 MB.

The Dual Cast BAR window size increases in powers of 2, starting from 1 MB. The address window size is determined by the quantity of Set bits, starting from bit 63 down to bit 20. For each bit that is a value of 1, the Copy TLP's Header Address bit is replaced by the corresponding Address bit in the **Dual Cast Low/High BARx Translation** registers, as illustrated in [Figure 9-10](#).

If bits [63:20] are all Set, the source window size is 1 MB. If bits [63:21] are all Set, and bit 20 is Cleared, the window size is 2 MB. When **Dual Cast High BARx Setup**[31] is Cleared, the corresponding Dual Cast BAR is disabled. [Table 9-16](#) lists example **Dual Cast Low/High BARx Setup** register values and the corresponding Dual Cast BAR Address window sizes.

**Table 9-15. Dual Cast High/Low BARx Setup Register Locations**

| Base Address Register | Port 0 Register Offset                       |                                               |
|-----------------------|----------------------------------------------|-----------------------------------------------|
|                       | Dual Cast Low Setup[31:0]<br>(Lower 32 Bits) | Dual Cast High Setup[31:0]<br>(Upper 32 Bits) |
| BAR0                  | 460h                                         | 464h                                          |
| BAR1                  | 478h                                         | 47Ch                                          |
| BAR2                  | 490h                                         | 494h                                          |
| BAR3                  | 4A8h                                         | 4ACh                                          |
| BAR4                  | 4C0h                                         | 4C4h                                          |
| BAR5                  | 4D8h                                         | 4DCh                                          |
| BAR6                  | 4F0h                                         | 4F4h                                          |
| BAR7                  | 508h                                         | 50Ch                                          |

**Figure 9-10. Dual Cast High/Low BARx Setup Register Example****Table 9-16. Dual Cast BARx Setup Register Address Window Sizing Examples**

| Dual Cast High BARx Setup[31:0] | Dual Cast Low BARx Setup[31:20] | Dual Cast BARx Window Size |
|---------------------------------|---------------------------------|----------------------------|
| 0000_0000h                      | XXXh                            | Disabled (default)         |
| FFFF_FFFFh                      | FFFh                            | 1 MB                       |
| FFFF_FFFFh                      | FFEh                            | 2 MB                       |
| FFFF_FFFFh                      | 000h                            | 4 GB                       |
| FFFF_FFFEh                      | 000h                            | 8 GB                       |

**Restrictions**

- Dual Cast BAR Address windows must not overlap one another.
- Dual Cast Source Address windows 0 through 7 can be mapped to any Port (including the upstream Port and NT Port); however, only Write TLPs that enter the PEX 8609 through the designated Dual Cast Source Port are subject to Dual Casting. (Refer to [Section 9.7.3.4.](#))
- Both the original forwarded TLP **and** Dual Cast Copy TLP must be acknowledged on their respective egress Ports, before the original incoming TLP can be retired.
- Dual Cast BAR regions can be coded only as 64-bit BARs. For regions under 4 GB, Dual Cast High **BARx** = 0000\_0000h.

### 9.7.3.4 Dual Cast Source Destination Port

The **Dual Cast Source Destination Port** register (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port; **Reserved** (RsvdP) for Dual Cast BAR Limit Lower register, offset 510h) is used to specify the Dual Cast Source and Destination Ports. Table 9-17 lists the bit definitions for this register. Bits not listed are **reserved** (zero).

**Table 9-17. Dual Cast Source Destination Port Register Definition  
(Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy  
NT Port; Reserved (RsvdP) for Dual Cast BAR Limit Lower  
register, offset 510h)**

| Bit(s) | Function                                                                                                                                                                                                                                                                                                                                                   |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3:0    | <b>Dual Cast Source Port #</b><br>Valid only when bit 8 ( <i>Dual Cast Source Port Enable</i> ) is Set.<br>Specifies the source (ingress) Port Number upon which Dual Cast BARs are applied.<br>Encodings not listed are reserved.<br>Refer to register offset 510h[3:0] for the associated Port Number values.                                            |
| 7:4    | <b>Dual Cast Destination Port #</b><br>Specifies the destination (egress) Port Number to which Dual Cast BAR Translation addresses are mapped, and to which Dual Cast Copy TLPs will be queued. Encodings not listed are reserved.<br>Refer to register offset 510h[7:4] for the associated Port Number values.                                            |
| 8      | <b>Dual Cast Source Port Enable</b><br>0 = Dual Cast applies to Write TLPs entering any Port on the Dual Cast Source Port. In that case, the field [3:0] ( <i>Dual Cast Source Port #</i> ) value is “Don’t Care.”<br>1 = Dual Cast applies only to Write TLPs entering the PEX 8609, by way of the Dual Cast Source Port Number specified in field [3:0]. |

## 9.7.4 Dual Cast Programming Example

In this example, we consider a PEX 8609 configured as x4, x1, x1, x1, x1, with Port 0 being the upstream Port (connected to Root Complex), and Ports 1, 5, 7, and 9 configured as Transparent downstream Ports. Port 1 maps to a block of physical memory at Base address AAA0\_0000h (32-bit addressing). Port 5 maps to a block of memory at Base address BBB0\_0000h. Ports 7 and 9 are not referenced in the remainder of this example.

For this example, the switch must be programmed such that Write TLPs entering Port 0 and addressed to Port 1 (in the range AAA0\_0000h to AAAF\_FFFFh) are Dual Cast (copied) to the memory that is mapped to Port 5, starting at address BBB0\_0000h.

### 9.7.4.1 Register Programming Steps

1. Program the **Dual Cast BAR0** registers with the Base address of the memory on Port 1.  
**Dual Cast Low BAR0**[31:0]=AAA0\_000Ch (*Note: [19:0] are hardwired to 0\_0000h.*)  
**Dual Cast High BAR0**[31:0]=0000\_0000h
2. Program the **Dual Cast BAR0 Setup** registers to specify the Dual Cast BAR window size (1 MB).  
**Dual Cast Low BAR0 Setup**[31:0]=FFF0\_0000h (*Note: [19:0] are hardwired to 0\_0000h.*)  
**Dual Cast High BAR0 Setup**[31:0]=FFFF\_FFFFh
3. Program the **Dual Cast BAR0 Translation** registers with the address of the memory on Port 5.  
**Dual Cast Low BAR0 Translation**[31:0]=BBB0\_0000h (*Note: [19:0] are hardwired to 0\_0000h.*)  
**Dual Cast High BAR0 Translation**[31:0]=0000\_0000h
4. Program the **Dual Cast Source Destination Port** register bits, as follows:  
**Dual Cast Source Destination Port**[3:0]=0h (Dual Cast Source Port 0)  
**Dual Cast Source Destination Port**[7:4]=5h (Dual Cast Destination Port 5)  
**Dual Cast Source Destination Port**[8]=1 (Dual Cast on Port 0 only)

At this point, all Write TLPs entering the PEX 8609 by way of Port 0, having addresses in the range AAA0\_0000h to AAAF\_FFFFh, will be copied to memory at Base address BBB0\_0000h. To verify that Dual Cast is enabled, try Clearing memory at address BBB0\_0000h, then write a non-zero pattern to memory at address AAA0\_0000h. A read of memory at BBB0\_0000h should now show what was written at address AAA0\_0000h.

## 9.7.5 Dual Cast to a Non-Transparent Destination Port

When the Dual Cast Destination Port is configured as Non-Transparent (NT), the Dual Cast Copy TLPs do not use the same Address Translation mechanism as original unicast TLPs that are routed to that Port. Where a unicast TLP uses the Address Translation mechanism in the NT Port (NT BAR), Dual Cast Copy TLPs are sent directly to the NT Port's Egress queue. Therefore, in applications where the Dual Cast Destination Port is the NT Port, the **Dual Cast Low/High BARx Translation** registers must be loaded with the physical Base address of the destination memory in the NT address domain.

## 9.7.6 Error Reporting of Failed Dual Cast Cycles

If either the PCI address-routed destination device or the device connected to the Dual Cast Destination Port fails to return an ACK for the Dual Casted Memory Write, the standard PCI Express Correctable Errors (Replay Timer Timeout on first transmission attempt, Replay Rollover Status after four failed attempts) are reported.

THIS PAGE INTENTIONALLY LEFT BLANK.

## Chapter 10 Integrated DMA Engine – DMA Mode Only

### 10.1 Features

The integrated Direct Memory Access (DMA) engine includes the following features:

- Four independent channels – DMA Channels 0, 1, 2, and 3
- Up to 3.0 GB/s<sup>a</sup> throughput, per channel
  - Designed to 100% use a PCI Express x4 5.0 GT/s (Gen 2) Link
    - One channel saturates the Link, in one direction
    - Two channels saturate the Link, in both directions
  - Fully pipelined Data Read and Data Write
- Transfer between any Port, including the same Port
- 16-byte Descriptor
  - Standard 16-byte Descriptor holds 48-bit Source address, 48-bit Destination address, 27-bit Transfer Size, and five Control bits
  - Extension 16-byte Descriptor holds upper 16-bit Source address and upper 16-bit Destination address, to allow 64-bit addressing
- 64-bit addressing
- Off-Chip Descriptor mode
  - Hides Descriptor fetch latency from Data transfer
  - If all four channels are enabled, each channel can fetch from 1 to 64, 16-byte Descriptors
- On-Chip Descriptor mode
  - 1 to 256 Descriptors can be programmed directly, on-chip
  - Read of system RAM not necessary to fetch Descriptors
- Controls, per Descriptor
  - *Valid* bit to indicate that DMA can work on a Descriptor
  - Programmable interrupt
  - Constant Source and/or Destination address
- Controls, per channel
  - Programmable Read Size, from 4 to 2,048 bytes
  - Programmable spacing between Reads
  - Programmable Traffic Class, Relaxed Ordering, No Snoop
  - Run/Pause DMA
  - DMA Abort
- DMA versus non-DMA traffic priority policy, using Traffic Class (TC)
  - TC/VC mapping allows DMA to proceed to a different queue than a non-DMA queue
  - Requires the support of two VC on the Link, to acquire different queues

---

*a. 3.0 GB/s includes all framing and protocol overhead, and is the Payload throughput for 64-byte Payload TLPs. Actual wire bandwidth approaches 4 GB/s, in each direction for a x4 Gen 2 Link.*

- DMA system debug
  - Done status per channel, visible to software
    - Current Descriptor
    - Actual Byte Count transferred
  - Optional Successful or Unsuccessful status, Invalidate Write Back, per Descriptor
  - Optional status (current Descriptor, Pause, Abort, and so forth), per channel
- DMA interrupt (Conventional PCI INTx or MSI) generated
  - Immediate Stop Done interrupt
  - If a Descriptor is directed to the end of another Descriptor
  - If an error occurs
  - If a Descriptor is invalid
  - Upon Pause Done
  - Upon Abort Done
  - 16 MSIs needed (four per channel)
  - 8 DMA interrupt Vectors (two per channel)
- Predictable Ordering – Per channel, in Descriptor order, for
  - DMA Reads
  - DMA Writes
  - DMA Completions
  - DMA interrupts
- DMA partial Completion combining
  - Combine partial Completions for one MRd tag
  - 64 tags
    - **One-Channel mode** – 63 tags for MRd, and one tag dedicated to Descriptor Read
    - **Four-Channel mode** – 60 tags for MRd (15 per channel), and four tags reserved for Descriptor Read (one per channel)
  - MRd Size programmable, up to Maximum Payload Size
  - MWrr Size = MRd Size

## 10.2 Terminology

Table 10-1 lists miscellaneous DMA and PCI Express-specific terminology used in this chapter.

**Table 10-1. Miscellaneous DMA- and PCI Express-Specific Terminology**

| Terms and Abbreviations | Description                                                                                                                                                                                    |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Data MRd                | Data Memory Read. Reading from the Source address, to gather data to transfer.                                                                                                                 |
| Data MWr                | Data Memory Write. Writing to the Destination address, to transfer Read data.                                                                                                                  |
| Descriptor              | 16 bytes of information that describes the DMA operation or instruction, <i>such as</i> the Source address to read, Destination address to write, and total Transfer Size.                     |
| DMA                     | Direct Memory Access.                                                                                                                                                                          |
| DMA Ring                | Physical location where the DMA Descriptors reside. When the last Descriptor is done, the pointer automatically moves to the location of the first Descriptor, creating a DMA Descriptor Ring. |
| Partial Completion      | In PCI Express, a single Read can have one or more Completions with data. If more than one Completion is returned, they are referred to as <i>Partial Completions</i> .                        |

## 10.3 General Description

DMA is a method used for moving data, without burdening the CPU. The CPU sets up DMA Descriptors to move data, turns On the DMA engine, and is then free to perform other processes while the DMA engine moves the data. The DMA engine can also interrupt the CPU and provide progress status at programmable intervals.

The PEX 8609's four DMA channels allow different, co-existing DMA transfers to run concurrently. A Descriptor provides the DMA channel with the necessary details for performing a transfer, after a DMA channel is turned On. The Descriptor is either programmed directly on the PEX 8609 ahead of time (DMA On-Chip Descriptor mode; refer to [Section 10.6.3](#)), or loaded from Host RAM (DMA Off-Chip Descriptor mode; refer to [Section 10.6.4](#)). If the Descriptor is loaded from Host RAM, multiple Descriptors can be loaded simultaneously, hiding the Descriptor Fetch time from the DMA movement. After the Descriptor is loaded, the Data Movement phase begins.

Each Descriptor includes a Source address, Destination address, Transfer Size, and Interrupt policy. Data is read from the Source address, by sending one or more Memory Reads at a programmable rate. The Read Completions are intercepted by the DMA engine at the Read Completion receiving Port (point of ingress) and turned into Writes to the Destination address. This process continues, until the Transfer Size is met, indicating that the Descriptor is done. The DMA engine can process and work on four Descriptors at a time. If one channel is enabled, the DMA engine will work on four Descriptors from that channel. If four channels are enabled, however, the DMA engine will concurrently work on only one Descriptor from each channel.

[Figure 10-1](#) illustrates the DMA operation sequence for a single channel. In this example, the DMA engine moves data from the main RAM to an endpoint. The CPU is used only in steps 1, 2, and 6; the remaining steps are performed by the DMA engine.

**Figure 10-1. DMA Operation Sequence**

## 10.4 DMA Usage Models

To help balance its workload, the CPU sets up Descriptors, then writes a 1 to the **DMA Channel  $x$  Control/Status** register *DMA Channel  $x$  DMA Start* bit(s) (DMA of Upstream Port, offsets 238h[3], 338h[3], 438h[3], and/or 538h[3]), to initiate the Data transfer. The Source address, Destination address, and Transfer Size describe the data movement. The DMA Controller generates and sends interrupts regarding DMA transfer's progress to the Host.

The PEX 8609's DMA supports transfers anywhere within its Address map (32- or 64-bit Memory space). The DMA engine can write to, and read from, any accessible upstream Memory space.

### 10.4.1 Statistics Gathering

Figure 10-2 illustrates a Host CPU that needs to process statistics gathered on  $M$  downstream ASICs. Rather than have the CPU read all the ASICs, the Host CPU sets up a DMA engine to periodically read the ASICs. By setting up  $N$  sets of  $M$  Descriptors, the CPU need only look at the statistics in Main memory, after  $N \times M$  Descriptors are done.

Figure 10-2. Statistics Gathering Usage Model

## 10.4.2 Peer-to-Peer Transfer

The DMA engine can move data from one downstream peer to another, without involving the chipset, thus avoiding upstream bottlenecks.

## 10.4.3 Move Data in Main Memory

The DMA engine can read Main memory, then write back to a different location, using either of the following methods:

- Gather scattered data in Main memory, then combine the data into one large block
- Gather a large chunk of data in Main memory, then break the data into smaller pieces

## 10.4.4 Endpoint

The DMA engine combined with the PEX 8609's Non-Transparent (NT) Port provides a powerful building block for an endpoint. Any device with a native PCI Express interface can be attached to the endpoint, then distributed across multiple Ports, to scale to larger capacity.

## 10.4.5 Interprocessor Communication

The DMA engine with the PEX 8609's NT Port can also communicate across two Host domains. Provided that a global Address table is available, each Host can write to or read from another Host's memory. (Refer to [Figure 10-3](#).)

**Figure 10-3. DMA and NT for Interprocessor Communication Usage Model**

## 10.5 Software Interface

Figure 10-4 illustrates a software view of the PEX 8609 with DMA. The PEX 8609 is composed of multiple PCI-to-PCI (P-P) bridges. The DMA Controller is seen as a Type 0 endpoint on Function 1 (F1) of the upstream device.

By having DMA as a separate function, software loads a driver for the DMA engine during discovery.

Software can reach the DMA Control registers and on-chip registers, using Memory-Mapped and/or Configuration Space Register (CSR) accesses (limited to 4 bytes for Reads and Writes).

A complete list of DMA-specific registers is provided in [Chapter 18, “DMA Interface Registers – DMA Mode Only.”](#)

**Figure 10-4. Software View of PEX 8609 with DMA**

PEX 8609 is a multi-function device

- Function 0 → P-to-P bridge
  - Transparent Switch model
  - No driver required
- Function 1 → DMA endpoint
  - Type 0 Configuration Header
  - Requires DMA driver (provided by PLX) \*
- DMA registers are memory-mapped for easy access

*\* At the time of this writing, only Microsoft Windows XP, Microsoft Vista, and Linux are supported.*

## 10.6 DMA Descriptors

Descriptors direct the work processed by the DMA engine. The DMA engine implements a Descriptor Ring format. This implementation allows the Descriptor pointer to automatically point to the first Descriptor's location, after the last Descriptor is processed. Figure 10-5 illustrates how Descriptors are stored within a Ring.

The Descriptors can be loaded directly onto the PEX 8609 ([DMA On-Chip Descriptor Mode](#)), or fetched during DMA runtime ([DMA Off-Chip Descriptor Mode](#)). Regardless of the mode, the Descriptors have the same format.

Each Descriptor is 16 bytes in length, and has a *Valid* bit, which is used to indicate whether the Descriptor contains valid data. If the Descriptor is invalid, the Descriptor remains unused.

The two Descriptor formats – Standard and Extended – are described in the sections that follow.

**Figure 10-5. Descriptor Ring**

- Descriptors are instructions for DMA
  - Written by CPU
  - Stored in a ring in Host Memory
  - OR–
  - Stored internal to the PEX 8609
- 16-byte standard format
  - Supports 32-bit Addressing
  - Control/Status information
- 16-byte extended format
  - Supports 64-bit Addressing
  - Control/Status information

## 10.6.1 Standard Descriptor Format

The Standard Descriptor format is the only Descriptor that requires programming to move data.

Figure 10-6 illustrates and describes the Standard Descriptor format.

**Figure 10-6. Standard Descriptor Format**

|         |                      |    |    |    |    |                      |    |    |    |    |    |    |    |    |    |    |                |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|---------|----------------------|----|----|----|----|----------------------|----|----|----|----|----|----|----|----|----|----|----------------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
|         | 31                   | 30 | 29 | 28 | 27 | 26                   | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15             | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

| DWord 2 | Lower DstAddr [31:0] |    |    |    |    |                      |    |    |    |    |    |    |    |    |    |    |                |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| DWord 1 | SrcAddr[47:32]       |    |    |    |    |                      |    |    |    |    |    |    |    |    |    |    | DstAddr[47:32] |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| DWord 0 | DV                   | D  | RC | WC | DF | Transfer Size [26:0] |    |    |    |    |    |    |    |    |    |    |                |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

### DWord 0 Descriptor Control

Bit 31 = *Descriptor Valid*.

Bit 30 = *Interrupt when Done with Descriptor*.

Bit 29 = *Hold Read Address Constant*.

Bit 28 = *Hold Write Address Constant*.

Bit 27 = *Descriptor Format* (0 = Standard).

*SrcAddr[1:0]* must match *DstAddr[1:0]* – both fields can be any value, as long as both values are the same.

## 10.6.2 Extended Descriptor Format

The Extended Descriptor format provides a method for changing the upper 16 bits of the Source and/or Destination address, using Descriptors, which enables the entire 64 bits of PCI Express Address space. Once programmed, the upper 16 bits remain the same for all subsequent Descriptors (until a new extended Descriptor is received). The Extended Descriptor also allows for the Descriptor Ring to move.

Figure 10-7 illustrates and describes the Extended Descriptor format.

**Figure 10-7. Extended Descriptor Format**

|         |                |    |    |      |    |          |    |    |    |    |    |    |    |    |    |    |                 |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|---------|----------------|----|----|------|----|----------|----|----|----|----|----|----|----|----|----|----|-----------------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
|         | 31             | 30 | 29 | 28   | 27 | 26       | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15              | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

| DWord 2 | Reserved       |    |    |      |    |          |    |    |    |    |    |    |    |    |    |    | DstPortNum Mask |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| DWord 1 | SrcAddr[63:48] |    |    |      |    |          |    |    |    |    |    |    |    |    |    |    | DstAddr[63:48]  |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| DWord 0 | DV             | SV | DV | Rsvd | DF | Reserved |    |    |    |    |    |    |    |    |    |    |                 |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

### DWord 0 Descriptor Control

Bit 31 = *Descriptor Valid*.

Bit 30 = *Upper SrcAddr Valid*.

Bit 29 = *Upper DstAddr Valid*.

Bit 28 = ***Reserved***.

Bit 27 = *Descriptor Format* (1 = Extended).

Bits [26:24] = ***Reserved***.

The Extended Descriptor must be valid (in the same way that the Standard Descriptor must be valid). When the Extended Descriptor is valid, it provides two functions, each of which can be enabled separately, by way of the corresponding *Valid* bit:

- **Bit 30 = 1** – The Upper Source Address bits, [63:48], takes this new value. All subsequent Descriptors will use the new Upper Source Address bits.

**Bit 30 = 0** – There is no change from the previous *SrcAddr[63:48]* bits value stored. If there was never a valid *SrcAddr Valid* bit, *SrcAddr[63:48]* will be Cleared.

- **Bit 29 = 1** – The Upper Destination Address bits, [63:48], can be modified. All subsequent Descriptors will use the new Upper Destination Address bits.

**Bit 29 = 0** – There is no change from the previous *DstAddr[63:48]* bits value stored. The initial value for *DstAddr[63:48]* is 0.

The *SrcPortNum Mask* bits [15:0] provide a means (one-hot mask) to check the routing for the generated DMA Memory Read Request. If one of the *SrcPortNum Mask* bits is Set, Data Reads are not allowed to be sent out from that Port. The one-hot mask applies to DMA Data Reads only – it does not apply to Descriptor Read/Write. *For example*, if bit 0 is Set, Read Requests are not allowed to exit on Port 0. Instead, any Read Requests targeted to exit on Port 0 will be dropped, and the DMA transaction will be terminated with a Source Port error.

The *DstPortNum Mask* bits [15:0] provide a means (one-hot mask) to check the routing for the DMA Memory Write Request generated. The one-hot mask applies to DMA Data Writes only – it does not apply to Descriptor Read/Write. If one of the *DstPortNum Mask* bits is Set, DMA Data Writes are not allowed to be sent out from that Port, in the same way as with the *SrcPortNum Mask* bits.

### 10.6.3 DMA On-Chip Descriptor Mode

In DMA On-Chip Descriptor mode (**DMA Global Control** register *DMA On-Chip Descriptor Mode* bit (DMA of Upstream Port, offset 1FCh[2]) is Set), an on-chip Descriptor RAM is visible to software. Any address in the Descriptor RAM can be read from or written to by software, four bytes at a time. The 256, 16-byte entries comprise 4 KB of CSR space. The 4-KB space starts at address offset 1000h. The DMA Descriptor RAM can be used as a Scratchpad RAM, regardless of whether DMA is enabled.

In On-Chip Descriptor mode, all Descriptors are directly programmed into this RAM, removing the need for the DMA engine to access Local memory to acquire Descriptors. (By comparison, in Off-Chip Descriptor mode, Descriptors from off-chip are copied onto this RAM, for internal consumption.)

While running On-Chip Descriptor mode, the *Valid* bit for the Descriptors is not Cleared. The Descriptor Ring Size indicates the quantity of on-chip Descriptors. When the last Descriptor is read, the DMA engine either stops, pauses, or delays, before looping back to the first Descriptor.

## 10.6.4 DMA Off-Chip Descriptor Mode

In DMA Off-Chip Descriptor mode (**DMA Global Control** register *DMA On-Chip Descriptor Mode* bit (DMA of Upstream Port, offset 1FCh[2]) is Cleared), the Descriptors are read from off-chip. The DMA channel must be programmed with a Descriptor Ring Base address and Descriptor Ring Size, before being activated.

In the Ring, the Descriptors are read, in order, starting at the Base address and moving up the address from there. When the end of the Ring is reached, the Descriptors continue being fetched from the start of the Ring again, in an endless loop. The delay of the Descriptor prefetch of the Descriptor Ring wraparound is programmable, by way of the **DMA Channel x Control/Status** register *DMA Channel x DMA Ring Delay Period* field(s) (DMA of Upstream Port, offsets 238h[15:13], 338h[15:13], 438h[15:13], and/or 538h[15:13]).

This mode can be used to prefetch Descriptors (1 to 256) that are not yet active. By prefetching the Descriptors, the DMA Data transfer can remain active 100% of the time. Without prefetching, after finishing one Descriptor, the DMA would have to wait for 300+ ns to fetch the next Descriptor, essentially losing bandwidth while waiting.

DMA Descriptors are prefetched four at a time<sup>a</sup> (4 x 16 bytes = 64 bytes common Cache Line Size). However, if the Prefetch limit is programmed to 1, only one Descriptor is prefetched at a time (1 x 16 bytes = 16 bytes common Cache Line Size).

If any Descriptor is invalid, then that Descriptor and any subsequent Descriptors are discarded. If enabled, an Invalid Descriptor interrupt is generated. Furthermore, the DMA Descriptor Invalid Status flag is Set (reported in the **DMA Channel x Control/Status** register *DMA Channel x DMA Descriptor Invalid Status* bit(s) (DMA of Upstream Port, offsets 238h[8], 338h[8], 438h[8], and/or 538h[8])), which prevents prefetching of Descriptors until the flag is Cleared.

*For example*, suppose that Descriptors at 400h, 410h, 420h, and 430h are prefetched. The Descriptor at 400h is valid, but the Descriptor at 410h is found to be invalid. As a result, Descriptors at 410h, 420h, and 430h are all discarded. The next Descriptor to prefetch is programmed to 410h, and the DMA Descriptor Invalid Status flag is Set.

---

*a. For example, if the Descriptor address is not 64-byte-aligned, it is aligned first, prior to being prefetched. Descriptors must be at 16-byte-aligned Address Boundary spaces. If the Descriptor is read at address 0A50\_0010h, then only three Descriptors are fetched, to access the 64-byte-aligned address of 0A50\_0040h.*

## 10.6.5 DMA Descriptor Writeback

When the DMA engine transmits the last byte to write, the Descriptor is done. The DMA engine can then be optionally programmed to write back to the Descriptor, to Clear the *Valid* bit (bit 31) and invalidate the Descriptor. The writeback is a 4-byte Write to the bottom of the Descriptor.

The DMA engine stops if it moves around the Descriptor Ring and encounters an invalid Descriptor.

## 10.7 DMA Alignment

Any Start address can be given to the Source address. However, the Destination address' two least significant bits (lsbs) must match the Source address' lsbs. This requirement – matching the two lsbs in the Source and Destination addresses – significantly simplifies the hardware.

For performance, two other alignment cases should be considered – 4-KB and Maximum Payload Size.

PCI Express does not allow Requests to cross a 4-KB Address Boundary space. For DMA, this affects the quantity of PCI Express accesses required for Reads and Writes. In the worst case, there can be three extra Reads and Writes per 4 KB, if the initial alignment is not optimal.

The PEX 8609's DMA engine always attempts to read the Maximum Programmed Read Size, which can be up to the system's Maximum Payload Size (MPS). If a Read does not start at an aligned MPS Address Boundary space, per Descriptor, there can be a Start and End Read that is less than the MPS, thereby impacting performance to a small degree.

*For example*, if a 256-byte (100h) Read starts at address A040\_0FF0h, there must be two different Read Requests – a 16-byte (10h) Read to reach the 4-KB Address Boundary space A040\_1000h, and then a 240-byte (F0h) Read to complete the transfer. Compare this to a 256-byte Read at the MPS-aligned address of A040\_0E00h – one Read is all that is needed for the entire 256 bytes. Additionally, the DMA engine can issue Read Requests with a Read Request smaller than the MPS, to align the Completions to a 64-byte boundary. This is necessary to combine the partial Completions received, into Writes with a Transfer Size equal to the MPS.

Writes have the same limitations for crossing the 4-KB Address Boundary space. To simplify the hardware, one Write is created for each Read. Therefore, Read Sizes must consider both the Read and Write 4-KB Address Boundary spaces.

To maximize performance, the Read and Write addresses should be 4-KB aligned (same 12 lsbs). Furthermore, to maintain maximum throughput, Reads should be Maximum Read Size (up to the MPS)-aligned.

[Table 10-2](#) describes a system with a 256-byte MPS, as well as DMA channel behavior for a given Transfer Size with an unaligned Start address on the source and destination. **DMA Channel x Current Descriptor Transfer Size** register *DMA Channel x Current Descriptor Transfer Size* field (DMA of Upstream Port, offsets [228h\[26:0\]](#), [328h\[26:0\]](#), [428h\[26:0\]](#), and/or [528h\[26:0\]](#)) value(s) indicate the quantity of bytes transferred. As can be observed from the table, there are cases in which the amount transferred is less than the MPS. This relates to the alignment to 64-byte Address Boundary space, as well as not crossing the 4-KB Address Boundary space. The table's *Action* column provides additional information regarding instances in which the amount transferred is less than 256 bytes. All Reads and Writes (in the table) are the same size.

[Figure 10-8](#) illustrates the data presented in [Table 10-2](#). The upper portion illustrates the Read stream, as well as the 4-KB Address Boundary spaces. Similarly, the lower portion illustrates the Write stream, as well as the 4-KB Address Boundary spaces. In this example, the Read 4-KB Address Boundary space precedes the Write 4-KB Address Boundary space.

Table 10-2. DMA Transfer with Unaligned Addresses

- System MPS = 256 bytes
  - Maximum Read Size = 256 bytes
- Source Address = 4E44h
  - Bits [1:0] = 00b
- Destination Address = 0BA8h
  - Bits [1:0] = 00b
- Transfer Size = 8,938 Bytes

| Action     | Read Address | Write Address | Bytes Transferred | Bytes Remaining |
|------------|--------------|---------------|-------------------|-----------------|
| Align 64B  | 4E44h        | 0BA8h         | 60                | 8,938           |
|            | 4E80h        | 0BE4h         | 256               | 8,878           |
| Read 4 KB  | 4F80h        | 0CE4h         | 128               | 8,622           |
|            | 5000h        | 0D64h         | 256               | 8,494           |
|            | 5100h        | 0E64h         | 256               | 8,238           |
| Write 4 KB | 5200h        | 0F64h         | 156               | 7,982           |
| Align 64B  | 529Ch        | 1000h         | 36                | 7,826           |
|            | 52C0h        | 1024h         | 256               | 7,790           |
|            |              |               |                   |                 |
| Read 4 KB  | 5FC0h        | 1D24h         | 64                | 4,462           |
|            | 6000h        | 1D64h         | 256               | 4,398           |
|            | 6100h        | 1E64h         | 256               | 4,142           |
| Write 4 KB | 6200h        | 1F64h         | 156               | 3,886           |
| Align 64B  | 629Ch        | 2000h         | 36                | 3,730           |
|            | 62C0h        | 2024h         | 256               | 3,694           |
|            |              |               |                   |                 |
|            | 6EC0h        | 2C24h         | 256               | 622             |
| Read 4 KB  | 6FC0h        | 2D24h         | 64                | 366             |

| Remainder  | 7100h        | 2E64h         | 46                | 46              |

Figure 10-8. DMA Alignment Example

## 10.8 Performance Considerations

The performance goal for the PEX 8609's DMA engine is 100% Link usage, in both directions for a x4 Gen 2 Link. With an average payload of 64 bytes, the PEX 8609 can sustain up to 3.0 GB/s per direction, per DMA channel.

This section consolidates the various methods for improving performance, into the following list.

*For optimal performance:*

- Set the MPS as high as possible (up to 2,048 bytes for the PEX 8609)
- Set the Maximum Read Size to the same value as the MPS
- Do one of the following:
  - Place Descriptors in on-chip Descriptor RAM, –or–
  - Program a large Transfer Size, per Descriptor, to minimize Descriptor fetching
- Align Source address and Destination address to MPS Address Boundary space
- Align Source address and Destination address to 4-KB Address Boundary space

For cases in which such high throughput hinders overall system performance, the DMA engine also implements the following alternative methods of restricting performance:

- [DMA Maximum Bandwidth](#)
- [DMA Maximum Round-Trip Read Time](#)
- [DMA and Non-DMA Policies](#)

### 10.8.1 DMA Maximum Bandwidth

A DMA channel's maximum bandwidth can be controlled, by Setting the Maximum Read Size and programming spacing between subsequent Reads. The spacing is Set, per channel, and is programmed in units of 4 ns.

*For example*, assume that the Maximum Read Size for a DMA channel is programmed to 256 bytes. Also, assume that the application requires the DMA channel to limit its bandwidth to 100 MB/s. In this case, the DMA channel must limit Data transfers to 256 bytes, every 2.56  $\mu$ s (256 bytes/100 MB/s). The 2.56  $\mu$ s period can be further broken down, into 4-ns units. The resulting value of 640 (in 4-ns units; 2.56  $\mu$ s/4 ns) is the value used to configure the **DMA Channel x Bandwidth** register *DMA Channel x DMA Clocks to Transfer* field(s) (DMA of Upstream Port, offsets [22Ch\[15:0\]](#), [32Ch\[15:0\]](#), [42Ch\[15:0\]](#), and/or [52Ch\[15:0\]](#)). As a result, the DMA channel does not consume more than 100 MB/s for its Data transfers. However, if the remainder of the DMA engine is not optimal (refer to [Section 10.8](#)), the DMA engine might fall short of the desired bandwidth.

## 10.8.2 DMA Maximum Round-Trip Read Time

It takes a round-trip delay, to receive Completion data after issuing a Read. As this time elapses, more data must be requested, to maintain maximum continuous throughput. Additional data can be requested by issuing larger, or more, Read Requests.

The Read Request Size sent by the DMA engine is programmable, and can be up to the system MPS. Per the *PCI Express Base r2.0*, all PCI Express systems support a minimum MPS of 128 bytes. Some systems can support up to the 2,048-byte MPS supported by the PEX 8609.

The quantity of DMA Reads depends upon the quantity of available DMA Read tags. Each DMA Read Request consumes a unique tag. The tag is used to pair the Read Completion with the original Read Request, to ensure correct sequencing of the Writes.

A total of 64 DMA Read tags are available. Each channel uses one tag for a Descriptor fetch, leaving the remaining tags available for Data Reads. The following summarizes the total quantity of available tags, based upon the quantity of active channels:

- **1 channel** – 63 Data Read tags + 1 Descriptor tag
- **2 channels** – (31 Data Read tags + 1 Descriptor tag) x 2
- **3 or 4 channels** – (15 Data Read tags + 1 Descriptor tag) x 4

The maximum round-trip time that a DMA channel can cover, while maintaining a fully used Link, is provided by the following formula:

$$\text{MaxRoundTrip} = (20 \text{ bytes} + \text{Read Request Size}) \times \text{MaxTags} / \text{LinkByteRate}$$

With a Maximum Payload Size of 256 bytes, two DMA channels, and two x4 PCI Express Links, the largest round-trip time that the DMA can cover, while maintaining 100% PCI Express usage, is  $(276) \times 31 / 4 \text{ GB/s} = 2,139 \text{ ns}$ .

## 10.8.3 DMA and Non-DMA Policies

The PEX 8609 can potentially have DMA and non-DMA traffic running concurrently. For each traffic type, there are several available methods, for controlling the Link usage ratio.

The first method – controlling the maximum bandwidth – is discussed in [Section 10.8.1](#). However, if it is necessary for the DMA engine to consume all available bandwidth, but on a lower priority than non-DMA traffic, use one of the following options:

- [DMA Traffic Class](#)
- [DMA Relaxed Ordering](#)
- [DMA No Snoop](#)

Within one channel, different DMA Requests (Descriptor Read/Write and Data Read/Write) can have programmable Relaxed Ordering and No Snoop.

### 10.8.3.1 DMA Traffic Class

Each DMA channel can be assigned a unique Traffic Class (TC). PCI Express allows eight different Traffic Classes (TC[7-0]), none of which are ordered against one another. Typical default non-DMA traffic uses only TC0. Setting a DMA channel to a non-zero Traffic Class provides the opportunity for different Quality of Service (QoS).

The PEX 8609 supports two Virtual Channels (VCs) – VC0 and VC1 – per physical Link. A TC can be mapped to any VC (with the exception of TC0, which can map only to VC0). The PEX 8609 allows three schemes for scheduling VC0 and VC1 traffic, by way of the **DMA Channel x Control/Status** register *DMA Channel x DMA Traffic Class* field(s) (DMA of Upstream Port, offsets [238h\[21:19\]](#), [338h\[21:19\]](#), [438h\[21:19\]](#), and/or [538h\[21:19\]](#)):

- VC0 higher priority
- VC0 lower priority
- VC0 equal priority

By putting DMA traffic onto VC1, VC1's traffic can be separated from VC0 (default) traffic, for any Link that supports two VCs.

### 10.8.3.2 DMA Relaxed Ordering

Each DMA channel can enable Relaxed Ordering on its Request TLPs. When the **DMA Channel x Control/Status** register Relaxed Ordering-related bits (DMA of Upstream Port, offsets 238h[25:22], 338h[25:22], 438h[25:22], and/or 538h[25:22]) are Set, the corresponding DMA Descriptor and Data Read and Write Requests will have the RO bit in the TLP Header Set, to take advantage of the PCI Express Relaxed Ordering rules.

Every PCI Express TLP Header has a *Relaxed Ordering* bit. If this bit is Set, Ordering rules are relaxed, and the Relaxed Ordering TLP can pass (or be passed) by another TLP.

The PEX 8609 looks only at the *Relaxed Ordering* bit for Completions. Completions with the *Relaxed Ordering* bit Set are sent to a different Egress queue than other traffic, and can therefore be scheduled at an earlier time.

For systems with only one VC, and where it is necessary to have DMA consume all available bandwidth while running at a lower priority than non-DMA traffic, the non-DMA traffic can Set the *Relaxed Ordering* bit.

### 10.8.3.3 DMA No Snoop

Each DMA channel can also program and enable the PCI Express *No-Snoop (NS)* bit to be Set in its TLP Headers. When the **DMA Channel x Control/Status** register No Snoop-related bits (DMA of Upstream Port, offsets 238h[29:26], 338h[29:26], 438h[29:26], and/or 538h[29:26]) are Set, the associated Descriptor and Data Read or Write Request TLPs have the NS bit Set in their PCI Express Headers, allowing applications that need this mechanism to enable No Snoop.

## 10.9 DMA Software Access

This section describes how to use software to access the DMA engine.

### 10.9.1 Configure a DMA Transfer

To configure a DMA transfer, the Descriptors must first be programmed. Descriptors can be programmed on- or off-chip, in local RAM.

With the Descriptors in place, the PEX 8609 must then be configured for DMA. After the **DMA Global Control** register *DMA Channel Mode* field (DMA of Upstream Port, offset 1FCh[1:0]) is used to select the quantity of DMA channels (one, two, or four; three channels is not an option), each channel can be independently programmed and started at any time.

With the channel ready to start, Set the **DMA Channel x Control/Status** register *DMA Channel x DMA Start* bit(s) (DMA of Upstream Port, offsets 238h[3], 338h[3], 438h[3], and/or 538h[3]), to turn On the DMA engine.

Table 10-3 lists the registers specific to programming the DMA Channels.

**Table 10-3. DMA Channel Programmable Registers**

| Register                                             | DMA Channel and Offset |      |      |      |
|------------------------------------------------------|------------------------|------|------|------|
|                                                      | 0                      | 1    | 2    | 3    |
| DMA Channel x Source Address Lower                   | 200h                   | 300h | 400h | 500h |
| DMA Channel x Source Address Upper                   | 204h                   | 304h | 404h | 504h |
| DMA Channel x Destination Address Lower              | 208h                   | 308h | 408h | 508h |
| DMA Channel x Destination Address Upper              | 20Ch                   | 30Ch | 40Ch | 50Ch |
| DMA Channel x Transfer Size                          | 210h                   | 310h | 410h | 510h |
| DMA Channel x Descriptor Ring Address Lower          | 214h                   | 314h | 414h | 514h |
| DMA Channel x Descriptor Ring Address Upper          | 218h                   | 318h | 418h | 518h |
| DMA Channel x Next Descriptor Ring Address Lower     | 21Ch                   | 31Ch | 41Ch | 51Ch |
| DMA Channel x Descriptor Ring Size                   | 220h                   | 320h | 420h | 520h |
| DMA Channel x Last Descriptor Address Lower          | 224h                   | 324h | 424h | 524h |
| DMA Channel x Last Descriptor Transfer Size          | 228h                   | 328h | 428h | 528h |
| DMA Channel x Bandwidth                              | 22Ch                   | 32Ch | 42Ch | 52Ch |
| DMA Channel x Maximum Prefetch Limit                 | 234h                   | 334h | 434h | 534h |
| DMA Channel x Control/Status                         | 238h                   | 338h | 438h | 538h |
| DMA Channel x Interrupt Control/Status               | 23Ch                   | 33Ch | 43Ch | 53Ch |
| DMA Channel x Error Header Log 0                     | 240h                   | 340h | 440h | 540h |
| DMA Channel x Error Header Log 1                     | 244h                   | 344h | 444h | 544h |
| DMA Channel x Error Header Log 2                     | 248h                   | 348h | 448h | 548h |
| DMA Channel x Error Header Log 3                     | 24Ch                   | 34Ch | 44Ch | 54Ch |
| DMA Channel x Device-Specific Error Status           | 250h                   | 350h | 450h | 550h |
| DMA Channel x Maximum Outstanding Read/Write Request | 254h                   | 354h | 454h | 554h |

## 10.9.2 DMA Pause

The DMA engine can be paused at any time, by Setting the **DMA Channel x Control/Status** register *DMA Channel x DMA Graceful Pause* bit(s) (DMA of Upstream Port, offsets 238h[0], 338h[0], 438h[0], and/or 538h[0]). This allows all current active Descriptors to complete (be done). No new Descriptors are prefetched when the DMA engine is paused.

After the current Descriptors are done, a Pause Done status flag (reported in the **DMA Channel x Control/Status** register *DMA Channel x DMA Graceful Pause Done Status* bit(s) (DMA of Upstream Port, offsets 238h[9], 338h[9], 438h[9], and/or 538h[9], is (are) Set)) communicates to software that the DMA channel is paused. Software can then read the next Descriptor pointer, to determine how far the DMA transfer has progressed.

To resume DMA operation from the Pause condition, Clear the *DMA Channel x DMA Graceful Pause* bit(s).

## 10.9.3 DMA Abort

In some cases, the DMA transfer might need to be aborted. *For example*, if a large transfer no longer needs to be completed, software can abort the DMA transfer, by Setting the **DMA Channel x Control/Status** register *DMA Channel x DMA Abort* bit(s) (DMA of Upstream Port, offsets 238h[1], 338h[1], 438h[1], and/or 538h[1]). When the *DMA Abort* bit is Set, no additional Requests are issued. This means that there are no more Descriptor fetches, nor Data Reads or Writes. Because no Descriptors are done, neither Descriptor interrupts nor writebacks are generated.

One loose end is waiting for all outstanding Reads to be done. To avoid having surprise Completions later, the DMA engine flushes all outstanding Read Requests on the scoreboard. It is not necessary to wait for the Received Completion data, because all Received Completion data is discarded.

An Abort Done status flag (reported in the **DMA Channel x Control/Status** register *DMA Channel x DMA Abort Done Status* bit(s) (DMA of Upstream Port, offsets 238h[10], 338h[10], 438h[10], and/or 538h[10], is (are) Set)) indicates that the Abort is done. This means that all outstanding Reads are done and the DMA status is up-to-date. Software can read the last Descriptor written, as well as the remaining bytes to be transferred, to determine how far the DMA transfer has progressed.

Software then Clears the Abort Done status flag and *DMA Abort* bit, before attempting to start another DMA transfer on the channel.

## 10.9.4 DMA Runtime Status

Once the DMA engine is running, runtime status can be viewed, without having to pause or abort the DMA transfer. This is accomplished by looking at the following information, which is recorded by the on-chip registers:

- Last Descriptor prefetched
- Last Descriptor finished
- Current Transfer Count
- Last Descriptor Transfer Size

In some cases, the CPU cannot probe down to the PEX 8609, to determine status, because it takes longer for the CPU to access the PEX 8609's internal registers than it takes to read from the local RAM. To support these cases, DMA status can be written to Local RAM, upon the Completion of each Descriptor.

Additionally, each Descriptor has a *Last Descriptor Transfer Size* bit. When Set, a Completion of the selected Descriptors generates an interrupt to the Host. Interrupts are grouped into two types for each channel – normal and error. The Descriptor Done interrupt is an example of a normal types of interrupt.

## 10.9.5 DMA Routing Check

The DMA engine can perform a routing authorization check, for Data Reads and Data Writes. A Data Read can be allowed or disallowed to read upstream, downstream, or out the NT Port. Similarly, a Data Write can be allowed or disallowed to write upstream, downstream, or out the NT Port.

If a Descriptor attempts to read from or write to a disallowed route, the TLP is dropped, and the Descriptor is skipped.

For further details regarding the interrupt options and errors generated, refer to [Section 10.9.6](#).

## 10.9.6 DMA Error Header Logging

The DMA engine has the capability, per channel, to log the Header of the first packet that causes difficulty. Difficulty is considered to be anything that causes the transfer to fail, including:

- Link is down
- Disallowed direction

Standard PCI Express errors (*such as* a malformed packet) can be trapped outside the DMA engine. If a Read Completion results in a malformed packet, the DMA engine reports a Read timeout, while the standard PCI Express logic reports the malformed packet. The Read Header and Malformed Packet Header are both logged.

## 10.9.7 DMA Current Status

The current status of a DMA transfer can be read by software (by reading the **DMA Control/Status** register), while the DMA engine is running or after it has stopped or paused for any reason.

THIS PAGE INTENTIONALLY LEFT BLANK.

### 11.1 Interrupt Support

The PEX 8609 supports the PCI Express interrupt model, which uses two mechanisms:

- INTx Interrupt Message-type emulation (compatible with the *PCI r3.0*-defined Interrupt signals)
- Message Signaled Interrupt (MSI), when enabled

For Conventional PCI compatibility, the PCI INTx emulation mechanism is used to signal interrupts to the System Interrupt Controller. This mechanism is compatible with existing PCI software, provides the same level of service as the corresponding PCI interrupt signaling mechanism, and is independent of System Interrupt Controller specifics. The PCI INTx emulation mechanism virtualizes PCI physical Interrupt signals, by using an in-band signaling mechanism, for the assertion and de-assertion of INTx interrupt signals.

In addition to PCI INTx-compatible interrupt emulation, the PEX 8609 supports the MSI mechanism. The PCI Express MSI mechanism is compatible with the MSI Capability defined in the *PCI r3.0*.

INTx and MSIs are mutually exclusive, on a per-Port basis; either can be enabled in a system (depending upon which interrupt type the system software supports, for assertion and de-assertion of interrupt signals), but never concurrently within the same domain. (Refer to the **PCI Command** register *Interrupt Disable* bit, offset 04h[10], and **MSI Capability** register, offset 48h, respectively.) The PEX 8609 does not convert received INTx Messages to MSI Messages.

The PEX 8609's external Interrupt output, **PEX\_INTA#**, indicates the assertion and/or de-assertion of the internally generated INTx signal:

- **Non-Hot Plug-triggered interrupts** – PEX\_INTA# assertion is controlled by the following **ECC Error Check Disable** register bits:
  - **NT mode only** – *Enable PEX\_INTA# Interrupt Output(s) for NT-Virtual Doorbell-Generated Interrupts* bit (NT Port Virtual Interface, or Port 0 if Port 0 is the NT Port, offset 1C8h[7])
  - *Enable PEX\_INTA# Interrupt Output(s) for GPIO-Generated Interrupts* (offset 1C8h[6])
  - *Enable PEX\_INTA# Interrupt Output(s) for Device-Specific Error-Triggered Interrupts* (offset 1C8h[5])

When any of these bits are Set, Device-Specific errors trigger PEX\_INTA# assertion; however, PEX\_INTA# assertion and INTx Message generation are mutually exclusive, on a per-Port basis.

- **Hot Plug or Link State-triggered INTx events** – PEX\_INTA# assertion is controlled by the **ECC Error Check Disable** register *Enable PEX\_INTA# Interrupt Output(s) for Hot Plug or Link State Event-Triggered Interrupts* bit (offset 1C8h[4]). When this bit is Set, Hot Plug or Link State events trigger PEX\_INTA# assertion; however, an INTx Message is not generated in this case. PEX\_INTA# assertion and INTx Message generation for Hot Plug or Link State cases are mutually exclusive, on a per-Port basis.

The NT Port Virtual and Link Interfaces can each independently support the interrupt mechanism (INTx or MSI) used in their respective domains. (Refer to [Section 15.7](#), “NT Port Interrupts,” for details.)

### 11.1.1 Interrupt Sources or Events

The PEX 8609 internally generated interrupt/Message sources include:

- Hot Plug or Link State events:
  - [Presence Detect Changed](#) (logical OR of PRSNT# (I/O Expander PRSNT# input), and SerDes Receiver Detect<sup>a</sup> on Lane(s) associated with that Port)
  - [Attention Button Pressed](#)
  - [Power Fault Detected](#)
  - [MRL Sensor Changed](#)
  - [Command Completed](#)
  - [Link Bandwidth Management Status](#)
  - [Link Autonomous Bandwidth Status](#)
- PCI Express Hot Plug events:
  - [Presence Detect Changed](#) (SerDes Receiver Detect<sup>a</sup> on Lane(s) associated with that Port)
  - [Data Link Layer State Changed](#)
- Device-Specific errors (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, unless noted otherwise):
  - Payload Link List RAM 1-Bit ECC error (offset 1C0h[1:0])
  - Payload Link List RAM 2-Bit ECC error (offset 1C0h[3:2])
  - Ingress Link List RAM 1-Bit ECC error (offset 1C0h[6, 4])
  - Ingress Link List RAM 2-Bit ECC error (offset 1C0h[7, 5])
  - Packet RAM 0 1-Bit ECC error (offset 1C0h[12, 11, 9, 8])
  - Packet RAM 0 2-Bit ECC error (offset 1C0h[18, 17, 15, 14])
  - Packet RAM 1 1-Bit ECC error (offset 1C0h[24, 23, 21, 20])
  - Packet RAM 1 2-Bit ECC error (offset 1C0h[30, 29, 27, 26])
  - Egress Completion FIFO Overflow (All Ports, offset 1CCh[0])
  - Destination Queue Linked List RAM 2-Bit ECC error (offset 1CCh[4])
  - Destination Queue Linked List RAM 1-Bit ECC error (offset 1CCh[6])
  - Source Queue Linked List RAM 1-Bit ECC error (offset 1CCh[9:8])
  - Source Queue Linked List RAM 2-Bit ECC error (offset 1CCh[11:10])
  - Retry Buffer 1-Bit ECC error (offset 1CCh[12])
  - Retry Buffer 2-Bit ECC error (offset 1CCh[13])
  - Descriptor RAM 1-Bit ECC error (offset 1CCh[17:16])
  - Descriptor RAM 2-Bit ECC error (offset 1CCh[19:18])

---

*a. The SerDes Receiver Detect mechanism is comprised of the **Even/Odd Port Receiver Detect Status** register Receiver Detected on Lane x bits (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port – Even Ports, offset 200h[27:24], and Odd Ports, offset 204h[27:24]) or Hot Plug PRSNT# (from external I<sup>2</sup>C I/O Expander) input for the Port.*

- Header (TLP ID) RAM 2-Bit ECC error (offset 1CCh[21:20])
- Header (TLP ID) RAM 1-Bit ECC error (offset 1CCh[25:24])
- PCI Express Correctable/Uncorrectable Link errors
- *DL\_Active* state change on the NT Port Link Interface (refer to [Section 15.7, “NT Port Interrupts”](#))
- General-Purpose Input/Output (GPIO) events (upstream Port only)
- Non-Transparent (NT) Doorbell events (refer to [Section 15.7, “NT Port Interrupts”](#))

The PEX 8609 externally generated interrupt/Message sources include INTx Messages from downstream devices.

[Table 11-1](#) lists the interrupt sources.

**Table 11-1. Interrupt Sources**

| Event/Error                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Device-Specific NT Port Link Interface errors and events | <ul style="list-style-type: none"> <li>NT Port Link Interface Correctable errors reported by the NT Port Virtual Interface (to the Host of the upstream Port domain), collectively flagged in the <b>Link Error Status Virtual</b> register <i>Link Side Correctable Error Status</i> bit (Port 0, when Port 0 is the NT Port, Virtual Interface Only, offset FE0h[0]), with specific errors indicated in the <b>Correctable Error Status</b> register (NT Port Link Interface, offset FC4h), if not masked both globally in the <b>Link Error Mask Virtual</b> register <i>Link Side Correctable Error Mask</i> bit (Port 0, when Port 0 is the NT Port, Virtual Interface Only, offset FE4h[0]), nor individually in the <b>Correctable Error Mask</b> register (NT Port Link Interface, offset FC8h).</li> <li>NT Port Link Interface Uncorrectable errors reported by the NT Port Virtual Interface (to the Host of the upstream Port domain), collectively flagged in the <b>Link Error Status Virtual</b> register <i>Link Side Uncorrectable Error Status</i> bit (Port 0, when Port 0 is the NT Port, Virtual Interface Only, offset FE0h[1]), with specific errors indicated in the <b>Uncorrectable Error Status</b> register NT Port Link Interface, offset FB8h), if not masked both globally in the <b>Link Error Mask Virtual</b> register <i>Link Side Uncorrectable Error Mask</i> bit (Port 0, when Port 0 is the NT Port, Virtual Interface Only, offset FE4h[1]), nor individually in the <b>Uncorrectable Error Mask</b> register (NT Port Link Interface, offset FBCh).</li> <li>NT Port Link Interface State change – Interrupt to the NT Port Virtual Interface Host, if enabled (not masked) by the <b>Link Error Mask Virtual</b> register <i>Link Side DL Active Change Mask</i> bit (Port 0, when Port 0 is the NT Port, Virtual Interface Only, offset FE4h[2]).</li> <li>Link Side Uncorrectable Error Message Drop interrupt to the NT Port Virtual Interface Host, if enabled (not masked) by the <b>Link Error Mask Virtual</b> register <i>Link Side Uncorrectable Error Message Drop Mask</i> bit (Port 0, when Port 0 is the NT Port, Virtual Interface Only, offset FE4h[3]). This feature supports applications using back-to-back NT Ports, where an Uncorrectable Error Message received (and properly dropped) by the NT Port Link Interface can trigger an interrupt to the NT Port Virtual Interface Host.</li> </ul> |
| NT-Virtual Doorbell events                               | <b>NT Port Virtual Interface IRQ Set/Clear</b> register (offsets C4Ch[15:0] and/or C50h[15:0]) bit is Set while the corresponding <b>NT Port Virtual Interface IRQ Set/Clear</b> register (offsets C54h[15:0] and/or C58h[15:0]) bit is Cleared.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| NT-Link Doorbell events                                  | <b>NT Link Interface IRQ Set/Clear</b> register (offsets C5Ch[15:0] and/or C60h[15:0]) bit is Set while the corresponding <b>NT Link Interface IRQ Set/Clear</b> register (offsets C64h[15:0] and/or C68h[15:0]) bit is Cleared.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## 11.1.2 Interrupt Handling

The PEX 8609 provides an Interrupt Generation module with each Port. The module reads the Request for interrupts from different sources and generates an MSI or PCI-compatible Assert\_INTx/Deassert\_INTx Interrupt Message. MSIs support a PCI Express edge-triggered interrupt, whereas Assert\_INTx and Deassert\_INTx Message transactions emulate PCI level-triggered interrupt signaling. The System Interrupt Controller functions include:

- Sensing Interrupt events
- Signaling the interrupt, by way of the INTx mechanism, and Setting the Interrupt Status bit
- Signaling the interrupt, by way of the MSI mechanism
- Handling INTx-type Interrupt Messages from downstream devices

## 11.2 INTx Emulation Support

The PEX 8609 supports PCI INTx emulation, to signal interrupts to the System Interrupt Controller. This mechanism is compatible with existing PCI software. PCI INTx emulation virtualizes PCI physical Interrupt signals, by using the in-band signaling mechanism.

PCI **Interrupt** registers (defined in the *PCI r3.0*) are supported. The *PCI r3.0* **PCI Command** register *Interrupt Disable* and **PCI Status** register *Interrupt Status* bits are also supported (offset 04h[10 and 19], respectively).

Although the *PCI Express Base r2.0* provides INTA#, INTB#, INTC#, and INTD# for INTx signaling, the PEX 8609 uses only INTA# for internal Interrupt Message generation, because it is a single-function device. However, incoming Messages from downstream devices can be of INTA#, INTB#, INTC#, or INTD# type. Internally generated INTA# Messages from the downstream Port are also re-mapped and collapsed at the upstream Port, according to the downstream Port's Device Number, with its own Device Number and Received Device Number from the downstream device.

When an interrupt is requested, the **PCI Status** register *Interrupt Status* bit is Set. If INTx interrupts are enabled (**PCI Command** register *Interrupt Disable* and **MSI Control** register *MSI Enable* bits, offsets 04h[10] and 48h[16], respectively, are Cleared), an Assert\_INTx Message is generated and transmitted upstream to indicate the Port interrupt status. For each interrupt event, there is a corresponding *Interrupt Mask* bit; an Interrupt Message can be generated only when the corresponding *Interrupt Mask* bit is Cleared. Software reads and Clears the event and *Interrupt Status* bit after servicing the interrupt.

A Port de-asserts INTx or **PEX\_INTA#** interrupts, in response to one or more of the following conditions:

- Port's **PCI Command** register *Interrupt Disable* bit (offset 04h[10]) is Set
- Corresponding *Interrupt Mask* bit is Set
- Upstream Port Link goes down (DL\_Down condition), or receives a Hot Reset (unless Hot Reset/DL\_Down Reset is disabled, by Setting the **Debug Control** register *Upstream Port and NT-Link DL\_Down Reset Propagation Disable* bit (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offset 1DCh[20]))
- Software Clears the corresponding *Interrupt Status* bit

## 11.2.1 INTx-Type Interrupt Message Re-Mapping and Collapsing

The upstream Port re-maps and collapses the INTx *virtual wires* received at the downstream Port, based upon the downstream Port's Device Number and Received INTx Message Requester ID Device Number, and generates a new Interrupt Message, according to the mapping defined in [Table 11-2](#).

Each virtual PCI-to-PCI bridge of a downstream Port specifies the Port Number associated with the INTx (Interrupt) Messages received or generated, and forwards the Interrupt Messages upstream.

A downstream Port transmits an Assert\_INTA/Deassert\_INTA Message to the upstream Port, due to a Hot Plug and/or PCI Express Hot Plug, Link State, GPIO, NT Port Doorbell interrupt, and/or Device-Specific error/event.

Internally generated INTx Messages always originate as type INTA Messages, because the PEX 8609 is a single-function device. Internally generated Interrupt INTA Messages from downstream Ports are re-mapped at the upstream Port to INTA, INTB, INTC, or INTD Messages, according to the mapping defined in [Table 11-2](#).

INTx Messages from downstream devices and from internally generated Interrupt Messages are ORed together to generate INTA, INTB, INTC, or INTD level-sensitive signals, and edge-detection circuitry in the upstream Port generates the Assert\_INTx and Deassert\_INTx Messages. The upstream Port then forwards the new Messages upstream, by way of its Link.

**Table 11-2. Downstream/Upstream Port INTx Interrupt Message Mapping**

| Device Number | At Downstream Port | By Upstream Port |
|---------------|--------------------|------------------|
| 0, 4, 8       | INTA               | INTA             |
|               | INTB               | INTB             |
|               | INTC               | INTC             |
|               | INTD               | INTD             |
| 1, 5, 9       | INTA               | INTB             |
|               | INTB               | INTC             |
|               | INTC               | INTD             |
|               | INTD               | INTA             |
| 6             | INTA               | INTC             |
|               | INTB               | INTD             |
|               | INTC               | INTA             |
|               | INTD               | INTB             |
| 7             | INTA               | INTD             |
|               | INTB               | INTA             |
|               | INTC               | INTB             |
|               | INTD               | INTC             |

### 11.2.1.1 Interrupt Re-Mapping and Collapsing – NT PCI-to-PCI Bridge Mode

In NT PCI-to-PCI Bridge mode, an NT Port Virtual Interface-generated interrupt is treated like an external event to the PCI-to-PCI bridge immediately upstream, for tracking purposes. In this mode, when the upstream Port receives an INTx Message from the NT Virtual Interface, the upstream Port re-mapping-collapsing logic performs double Swizzling, one based upon the NT Port Virtual Interface's Captured Device Number, and another based upon the virtual downstream Port (PCI-to-PCI) Device Number.

If software asserts a [Secondary Bus Reset](#) to this PCI-to-PCI bridge, the PCI-to-PCI bridge de-asserts the NT Port Virtual Interface interrupt.

## 11.3 MSI Support

One of the interrupt schemes supported by the PEX 8609 is the MSI mechanism, which is required for PCI Express devices. The MSI method uses Memory Write transactions to deliver interrupts. MSIs are edge-triggered interrupts.

**Note:** *MSIs and INTx are mutually exclusive, on a per-Port basis. The mechanisms that generate these types of interrupts **cannot** be simultaneously enabled.*

### 11.3.1 MSI Operation

At configuration time, system software traverses the function Capability list. If a [Capability ID](#) of 05h is found, the function implements MSIs. System software reads the **MSI Capability** structure registers, to determine function capabilities.

The **MSI Control** register [Multiple Message Capable](#) field (offset 48h[19:17]) default value is 010b, which indicates that the PEX 8609 requests up to four MSI Vectors (Address and Data). When the register's [Multiple Message Enable](#) field (offset 48h[22:20]) is Cleared (default), only one Vector is allocated, and therefore, the PEX 8609 can generate only one Vector for all errors or events. When system software writes a non-zero value to the [Multiple Message Enable](#) field, multiple-Vector support is enabled (the quantity of Vectors supported is dependent upon the value). [Table 11-3](#) lists the supported MSI Vector types.

**Table 11-3. Supported MSI Vector Types**

| Vector Type                                        | Transparent Mode | NT Mode           |                | DMA Mode |
|----------------------------------------------------|------------------|-------------------|----------------|----------|
|                                                    |                  | Virtual Interface | Link Interface |          |
| Power Management, or Hot Plug or Link State events | ✓                | ✓                 |                |          |
| Device-Specific errors                             | ✓                | ✓                 | ✓              |          |
| GPIO interrupts                                    | ✓                | ✓                 |                |          |
| NT Doorbell interrupts                             |                  | ✓                 | ✓              |          |
| <b>DMA (TBD)</b>                                   |                  |                   |                |          |

System software initializes the MSI Address registers (offsets 4Ch and 50h) and **MSI Data** register (offset 54h), with a system-specified Vector. After system software enables the MSI function (by Setting the **MSI Control** register *MSI Enable* bit, offset 48h[16]), when an Interrupt event occurs, the Interrupt Generation module generates a DWord Memory Write to the address specified by the **MSI Address** (lower 32 bits of the *Message Address* field) and **MSI Upper Address** (upper 32 bits of the *Message Address* field) register contents (offsets 4Ch and 50h, respectively). The single DWord Payload includes zero (0) for the upper two bytes, and the lower two bytes are taken from the **MSI Data** register. The **MSI Control** register *Multiple Message Enable* field (offset 48h[22:20]) can be programmed to any value of 000b through 111b. When programmed to 010b through 111b, the lower three bits of Message data are changed to indicate the general type of interrupt event that occurred. (Refer to Table 11-3.)

The quantity of MSI Vectors generated is dependent upon the quantity enabled, as follows:

- If **one** MSI Vector is enabled (default), all interrupt categories generate the same MSI Vector
- If **two** MSI Vectors are enabled, Device-Specific errors generate their own MSI Vector, while all other categories are combined and generate the same Vector
- If **four** MSI Vectors are enabled, each interrupt category generates its own MSI Vector

If a non-masked Interrupt event occurs before system software Sets the *MSI Enable* bit, normally (but unlike Conventional PCI interrupts, which are level-triggered), an MSI packet is sent immediately after software Sets the *MSI Enable* bit, to notify the system of the prior event. Alternatively, MSIs for prior events can be disabled, on a per-Port basis, by Setting the **ECC Error Check Disable** register *Disable Sending MSI if MSI Is Enabled after Interrupt Status Set* bit (offset 1C8h[8]).

When the error or event that caused the interrupt is serviced, the PEX 8609 can generate a new MSI Memory Write as a result of new events. Because MSIs are edge-triggered events, four bits are provided for masking the errors (**MSI Mask** register *Interrupt Mask* bits, offset 58h[3:0]). A new MSI can be generated only after the *Interrupt Mask* bits are serviced. System software should mask these bits when the MSI event is being processed.

The **MSI Control** register *MSI 64-Bit Address Capable* bit is enabled (offset 48h[23], is Set), by default.

If the serial EEPROM and/or I<sup>2</sup>C/SMBus Clears the bit, the **MSI Capability** structure is reduced by 1 DWord (*that is*, register offsets 54h, 58h, and 5Ch change to 50h, 54h, and 58h, respectively).

### 11.3.1.1 NT PCI-to-PCI Bridge Mode MSIs – NT PCI-to-PCI Bridge Mode

In NT PCI-to-PCI Bridge mode, MSI TLPs are not generated if the **PCI Command** register *Bus Master Enable* bit (offset 04h[2]) is Cleared in the upstream Port, NT Port Virtual Interface, and Virtual Downstream PCI-to-PCI bridge.

### 11.3.2 MSI Capability Registers

For details, refer to Section 14.8, “MSI Capability Registers (Offsets 48h – 64h).”

## 11.4 PEX\_INTA# Interrupts

PEX\_INTA# Interrupt output is enabled when the following conditions exist:

- INTx Messages are enabled (**PCI Command** register *Interrupt Disable* bit, offset 04h[10], is Set) and MSIs are disabled (**MSI Control** register *MSI Enable* bit, offset 48h[16], is Cleared)
- PEX\_INTA# outputs are enabled for the following interrupts, when the **ECC Error Check Disable** register bit associated with that interrupt is Set:
  - **NT mode only** – *Enable PEX\_INTA# Interrupt Output(s) for NT-Virtual Doorbell-Generated Interrupts* bit (NT Port Virtual Interface, or Port 0 if Port 0 is the NT Port, offset 1C8h[7])
  - *Enable PEX\_INTA# Interrupt Output(s) for GPIO-Generated Interrupts* bit (offset 1C8h[6])
  - *Enable PEX\_INTA# Interrupt Output(s) for Device-Specific Error-Triggered Interrupts* bit (offset 1C8h[5])
  - *Enable PEX\_INTA# Interrupt Output(s) for Hot Plug or Link State Event-Triggered Interrupts* bit (offset 1C8h[4])

The three interrupt mechanisms, listed below, are mutually exclusive modes of operation, on a per-Port basis, for all interrupt sources:

- Conventional PCI INTx Message generation
- Native MSI transaction generation
- Device-Specific PEX\_INTA# assertion

PEX\_INTA# assertion (Low) indicates that the PEX 8609 detected one or more of the events and/or errors (if not masked) listed in [Table 11-1](#).

**Note:** *PEX\_INTA# assertion and INTx messaging are mutually exclusive for a given interrupt event. When MSIs are enabled (offset 48h[16], is Set), both PEX\_INTA# and INTx are disabled for PEX 8609 internally generated interrupts. The forwarding of external INTx Messages received from a downstream Port to the upstream Port is always enabled.*

## 11.5 General-Purpose Input/Output

The PEX 8609 contains 19 GPIO balls and associated registers, that can be programmed to function as GPIO and/or Interrupt inputs. Default functionality is GPIO inputs; however, serial EEPROM, I<sup>2</sup>C/SMBus, and/or software can program the GPIO registers to define functionality for each I/O, to be used as GPIO, Interrupt inputs, or Serial Hot Plug **PERST#** outputs.

Table 11-4 lists the registers used for GPIO functionality.

**Table 11-4. Registers Used for GPIO Functionality**

| Register Offset <sup>a</sup> | Register Name                        |
|------------------------------|--------------------------------------|
| 62Ch                         | GPIO 0_15 Direction Control          |
| 630h                         | GPIO 16, 29, 30 Direction Control    |
| 638h                         | GPIO 0_16, 29, 30 Input De-Bounce    |
| 63Ch                         | GPIO 0_15 Input Data                 |
| 640h                         | GPIO 16, 29, 30 Input Data           |
| 644h                         | GPIO 0_15 Output Data                |
| 648h                         | GPIO 16, 29, 30 Output Data          |
| 64Ch                         | GPIO 0_16, 29, 30 Interrupt Polarity |
| 650h                         | GPIO 0_16, 29, 30 Interrupt Status   |
| 654h                         | GPIO 0_16, 29, 30 Interrupt Mask     |

a. All registers listed in this table are located in Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port.

THIS PAGE INTENTIONALLY LEFT BLANK.

## Chapter 12 Hot Plug Support

### 12.1 Introduction

Hot Plug capability allows board insertion and removal from a running system, without adversely affecting the system. Boards are typically inserted or removed to repair faulty boards or re-configure the system without system down time. Hot Plug capability allows systems to isolate faulty boards in the event of a failure.

### 12.2 Hot Plug Features

The following are the PEX 8609 Hot Plug features:

- Hot insertion and removal
- All Ports are Hot Plug-capable, through I<sup>2</sup>C (Serial Hot Plug Controller on every Port)
- Serial Hot Plug Controller with I<sup>2</sup>C I/O Expander on seven Transparent downstream Ports
- Insertion and removal of PCI Express boards, without removing system power
- Generates Power Management Event (PME) on a Hot Plug event in a sleeping system
- Electromechanical Interlock Control feature available on Serial Hot Plug-capable Ports

### 12.3 Hot Plug Signals

The on-chip signals for Serial Hot Plug Controller support are defined in [Section 3.4.2, “Serial Hot Plug Signals.”](#) In addition to the set of on-chip Serial Hot Plug signals, the PEX 8609 supports Serial Hot Plug signals to and from the I<sup>2</sup>C I/O Expander, which are used with Serial Hot Plug-capable Transparent downstream Ports. (Refer to [Section 12.6.2.](#))

### 12.4 Hot Plug Registers

All Transparent downstream Ports include identical sets of Hot Plug registers.

The PCI Express Hot Plug Configuration, Capability, Command, Status, and Event registers are described in [Section 14.9, “PCI Express Capability Registers \(Offsets 68h – A0h\).”](#)

Device-Specific Hot Plug configuration features are programmable in register offset [1E0h](#) of each Transparent downstream Port.

### 12.5 Hot Plug Interrupts

Refer to [Chapter 11, “Interrupts,”](#) for details.

## 12.6 Serial Hot Plug Controller

**Note:** The I<sup>2</sup>C Master interface is described in this section. The Master capabilities are limited to the Serial Hot Plug Controller.

Using I/O Expander ICs sitting on an I<sup>2</sup>C Bus, the PEX 8609 has the option of Hot Plug capability on all its Transparent downstream Ports. Figure 12-1 illustrates the internal Serial Hot Plug Controller interface. The Serial Hot Plug Controller controls the output Ports on the I/O Expanders and retrieves the Port status, such as device connect status, Power Fault, and MRL Sensor position, from all I/O Expanders. When there is an input change to an I/O Expander, an INTx interrupt from an I/O Expander goes Low and the PEX 8609 reads the I/O Expander. When an I/O Expander output Port requires updating with a new value, the PEX 8609 writes to the I/O Expander through the I<sup>2</sup>C Bus.

**Figure 12-1. Serial Hot Plug Interface Diagram**

## 12.6.1 Hot Plug Operations by way of I<sup>2</sup>C I/O Expander

When software issues a Slot Power On command, the Serial Hot Plug Controller issues an I<sup>2</sup>C Write to the I/O Expander, to assert the **PWREN** output on the I/O Expander, and thereby turn On the power. After the Write is complete and the  $T_{pepv}$  time has elapsed, the Serial Hot Plug Controller issues another Write to the I/O Expander, to assert its **RECLKEN#** output, and thereby turn On the Reference Clock (REFCLK) at the slot.

After the RECLKEN# output is asserted, the Serial Hot Plug Controller issues another Write, to de-assert the I/O Expander **PERST#** output to the slot. If there are commands, *such as* Attention or Power LED changes along with the Power Control command, the Serial Hot Plug Controller includes the LED output value change, along with these Writes, to change the LED status. The same procedure applies to other commands, *such as* Port Power Off. After the Serial Hot Plug Controller completes all Write operations, it Sets the *Command Completed* bit. When another command is issued before the current command completes, the results are undefined. With a 100-kHz I<sup>2</sup>C clock, the time required to complete one Write operation to an I/O Expander is approximately 1 ms.

## 12.6.2 I<sup>2</sup>C I/O Expander Parts Selection and Pin Definition

Two types of I<sup>2</sup>C I/O Expanders can be used for Serial Hot Plug:

- **16-bit device** – For the 16-bit device, the 7-bit I<sup>2</sup>C address must be 0100\_XXXb; a Maxim MAX7311, NXP PCA9555, or TI PCA9555 is recommended. I/O Expander addresses must begin with the lowest address, and increment sequentially (corresponding to increasing PEX 8609 Port Numbers), for each device. For MAX7311 (which supports more addresses than the other 16-bit devices), the 7-bit I<sup>2</sup>C addresses can be in two ranges, 0100\_XXXb and 1010\_XXXb. All 16 I/O pins of the devices are used for one Port. A 16-bit device supports one Serial Hot Plug Port. (Refer to [Figure 12-2](#).)

For further details, refer to the manufacturer's data sheets for the Maxim MAX7311, NXP PCA9555, or TI PCA9555.

- **40-bit device** – For the 40-bit device, the 7-bit I<sup>2</sup>C address must be within two ranges, 0100\_XXXb and 1010\_XXXb; an NXP PCA9698 is recommended. I/O Expander addresses must begin with the lowest address, and increment sequentially (corresponding to increasing PEX 8609 Port Numbers), for each device. The lower 32 I/O pins are used for two Ports. A 40-bit device can support two sets of Serial Hot Plug pins. The two sets are indicated with suffix PX and PY, in [Figure 12-3](#).

For further details, refer to the manufacturer's data sheet for the NXP PCA9698.

The PEX 8609 can support multiple 16- or 40-bit I/O Expanders, but not both types concurrently, to provide Hot Plug services on all Transparent downstream Ports. (Refer to the **Power Management Hot Plug User Configuration** register *40-Pin I/O Expander Enable* bit (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port, offset [1E0h\[17\]](#))). Each I/O Expander has a 3-bit address, and thus one PEX 8609 can support up to seven external I/O Expanders.

[Table 12-1](#) defines the external I<sup>2</sup>C I/O Expander pins, in location order.

**Table 12-1. External I<sup>2</sup>C I/O Expander Pin Definitions, by Location**

| Signal Name         | Direction | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Location                                 |                                      |

## 12.6.3 Serial Hot Plug Port Enumeration and Assignment

Each I/O Expander has a 7-bit address; the PEX 8609 scans for sequential I<sup>2</sup>C addresses, starting with address 40h.

After `PEX_PERST#` de-asserts and the serial EEPROM (if present) load completes, the Serial Hot Plug Controller accesses all I<sup>2</sup>C addresses to perform the I/O Expander hunt, to determine the presence of external I/O Expander devices. If the Controller receives an Acknowledge Control Packet (ACK) from the I/O Expander, it remembers the presence of an external I/O Expander device, which is assigned to one of the Transparent downstream Ports.

**Note:** *The PEX 8609 can support up to seven downstream Ports. Every Transparent downstream Port can support Hot Plug.*

To simplify the Serial Hot Plug Port enumeration and assignment, the virtual Serial Hot Plug Port definition is provided as follows, and the mapping between virtual Serial Hot Plug Port and PEX 8609 Ports is provided later.

Table 12-2 defines the virtual Serial Hot Plug Port for a 16-bit device, such as a Maxim MAX7311, NXP PCA9555, or TI PCA9555. Table 12-3 defines the virtual Serial Hot Plug Port for a 40-bit device, such as an NXP PCA9698.

The following three types of Ports are not Serial Hot Plug-capable, and therefore are not assigned a virtual Serial Hot Plug Port Number:

- Disabled Ports, due to Port configuration
- Upstream Port
- NT Port

**Table 12-2. Virtual Serial Hot Plug Port Definition for 16-Bit Device**

THIS PAGE INTENTIONALLY LEFT BLANK.

### 13.1 Overview

The PEX 8609 Power Management (PM) features provide the following services:

- Mechanisms to identify PM capabilities
- Ability to transition into certain PM states
- Notification of the current PM state of each Port
- Support for the option to wakeup the system upon a specific event

The PEX 8609 supports hardware-autonomous PM and software-driven D-State PM. The switch also supports the L0s and L1 Link PM states in hardware-autonomous Active State Power Management (ASPM), as well as the L1, L2/L3 Ready, and L3 Link PM states in Conventional PCI-compatible PM. D0, D3hot, and D3cold Device PM states are supported in Conventional PCI-compatible PM. Because the PEX 8609 does not support Vaux, Power Management Event (PME) generation from the D3cold Device PM state is **not supported**.

The PM module interfaces with a Physical Layer (PHY) electrical sub-block, to transition the Link state into a low-power state, when the module receives a Power State Change Request from a downstream component, or an internal event forces the Link state entry into low-power states in hardware-autonomous ASPM mode. PCI Express Link states are not directly visible to Conventional PCI Bus driver software; however, they are derived from the PM state of the components residing on those Links.

Figure 13-1 provides a functional block diagram of the PEX 8609 PM module.

**Figure 13-1. PM Module Functional Block Diagram**

## 13.2 Power Management Features

- *PCI Express Base r2.0*-compliant
- *PCI Power Mgmt. r1.2*-compliant
- Link Power Management States (*L-States*; also referred to as *Link PM states*)
  - PCI Bus Power Management – L1, L2/L3 Ready, and L3 (Vaux is **not supported**)
  - Active State Power Management (ASPM) – L0s and L1
- Device Power Management State (*D-States*; also referred to as *Device PM states*)
  - D0 (D0uninitialized and D0active) and D3 (D3hot and D3cold) support
- Power Management Event (PME) support from D3hot
- PME due to Hot Plug and/or PCI Express Hot Plug events
- Forwards PME\_Turn\_Off broadcast messages
- Supports Clock Power Management using CLK\_REQ#
- Implements Gen 2-specific Control and Status registers, and associated interrupts
- Supports ASPM L0s, ASPM L1, PCI PM L1, and L2/L3 Ready Link PM states in NT mode

## 13.3 Power Management Capability

### 13.3.1 Device Power Management States

The PEX 8609 supports the PCI Express PCI-PM D0 and D3hot Device PM states. The D1 and D2 Device PM states, which are optional in the *PCI Express Base r2.0*, are **not supported** by the PEX 8609.

The D3hot Device PM state can be entered from the D0 Device PM state, when system software programs the Port's **PCI Power Management Status and Control** register *Power State* field (offset 44h[1:0]) to 11b. The D0uninitialized Device PM state can be entered from the D3hot Device PM state when system software Clears the Port's *Power State* field.

#### 13.3.1.1 D0 Device Power Management State

The D0 Device PM state is divided into two distinct sub-states – *uninitialized* and *active*. When power is initially applied to a PCI Express component, it defaults to the D0uninitialized Device PM state. The component remains in the D0uninitialized Device PM state until the serial EEPROM load and initial Link training completes.

A device enters the D0active Device PM state when system software Sets any combination of the **PCI Command** register *Bus Master Enable*, *Memory Access Enable*, and/or *I/O Access Enable* bits (offset 04h[2, 1, and/or 0], respectively).

#### 13.3.1.2 D3hot Device Power Management State

Once in the D3hot Device PM state, the PEX 8609 can later be transitioned into the D3cold Device PM state, by removing power from its Host component. Functions that are in the D3hot Device PM state can be transitioned, by software, to the D0uninitialized Device PM state. When in the D3hot Device PM state, Hot Plug or Link State operations cause a PME in the PEX 8609.

Only Type 0 Configuration accesses are allowed in the D3hot Device PM state. Memory and I/O transactions result in an Unsupported Request (UR). Completions flowing in either direction are not affected.

Type 1 transactions flowing toward a PEX 8609 Port in the D3hot Device PM state are terminated as URs. Type 0 Configuration transactions complete successfully. When the PEX 8609 upstream Port is programmed to the D3hot Device PM state, the Port initiates Conventional PCI-PM L1 Link PM state entry.

### 13.3.2 Link Power Management States

PEX 8609 components hold their upstream Link and downstream Links in the L0 Link PM state when they are in the standard operational state (Conventional PCI-PM state is in the D0active Device PM state). ASPM defines a mechanism for components in the D0 Device PM state, to reduce Link power by placing their Links into a low-power state and instructing the other end of the Link to do likewise. This allows hardware-autonomous, dynamic Link power reduction beyond what is achievable by software-only-controlled PM. [Table 13-1](#) defines the relationship between a component's Power state and its upstream Link. [Table 13-2](#) defines the relationship between Link PM states and power-saving actions.

Conventional PCI PM, and the L1 and L2/L3 Ready Link PM states are controlled by system software programming the PEX 8609 into the D3hot Device PM state, and subsequently causing the Root Complex to broadcast the PME\_Turn\_Off Message to the downstream hierarchy.

**Table 13-1. Relationship between Component Power State and Upstream Link**

| Downstream Component Device PM State | Permissible Upstream Component Device PM State | Permissible Interconnect Link PM State |
|--------------------------------------|------------------------------------------------|----------------------------------------|
| D0                                   | D0                                             | L0, L0s, L1 (optional) – ASPM.         |
| D3hot                                | D0 to D3hot                                    | L1, L2/L3 Ready.                       |
| D3cold (no Vaux)                     | D0 to D3cold                                   | L3 (off). Zero power.                  |

**Table 13-2. Relationship between Link PM States and Power-Saving Actions**

| Link PM State | Power-Saving Actions                                                      |
|---------------|---------------------------------------------------------------------------|
| Tx L0s        | PHY Tx Lanes are in a high-impedance state.                               |
| Rx L0s        | PHY Rx Lanes in a low-power state.                                        |
| L1            | PHY Tx and Rx Lanes are in a low-power state.<br>FC timers are suspended. |
| L2/L3 Ready   | PHY Tx and Rx Lanes are in a low-power state.<br>FC timers are suspended. |
| L3 (D3cold)   | Component is fully powered Off.                                           |

### 13.3.3 PCI Express Power Management Support

The PEX 8609 supports PM features required in the *PCI Express Base r2.0*. [Table 13-3](#) lists supported and non-supported features and the register bits/fields used for configuration or activation.

**Table 13-3. Supported PCI Express PM Capabilities**

| Register |                                             | Description                                                                                                                                                                                     | Supported |    |

- a. Because the PEX 8609 does not consume auxiliary power, this bit is not sticky, and is always Cleared at power-on reset.
- b. With no serial EEPROM nor previous I<sup>2</sup>C programming, Reads return 00h for the **Data** and **Data Scale** registers (for all Data Selects).

- a. Because the PEX 8609 does not consume auxiliary power, this bit is not sticky, and is always Cleared at power-on reset.
- b. With no serial EEPROM nor previous I<sup>2</sup>C programming, Reads return 00h for the **Data** and **Data Scale** registers (for all Data Selects).

## 13.4 Power Management Tracking

**Note:** *NT Port Link Interface entry and exit to ASPM and Conventional PCI PM-compatible power states do not depend upon the Transparent upstream nor downstream Port power states or traffic. They are solely dependent upon the NT Port Link Interface's traffic conditions.*

Upstream Port logic tracks the Link status of each downstream and upstream Port Link, to derive the following conditions:

- Upstream Port enters the L0s Link PM state when all enabled downstream Receivers are in the L0s Link PM state or deeper, or in a Link Down state.
- Upstream Port enters the active L1 Link PM state, only when all downstream Ports are in the active L1 Link PM state or deeper, or the Link is down.
- When a downstream Port is in the active L1 Link PM state and an ASPM L1 Link PM state exit is occurring in the downstream Port, the upstream Port exits the L1 Link PM state.
- When the upstream Port is in the active L1 Link PM state and an active L1 Link PM state exit is occurring, due to Receiver Electrical Idle exit, the downstream Port exits the L1 Link PM state.
- When a PME\_TO\_Ack Message is received only on all active (not in Link Down) downstream Ports, a PME\_TO\_Ack Message is issued toward the upstream Port. The NT Port Virtual Interface is marked as being in the *DL\_Down* state.
- When all downstream Ports are in the L2/L3 Ready Link PM or Link Down state, the upstream Port transmits PM\_ENTER\_L23 DLLPs toward the Root Complex.

## 13.5 Power Management Event Handler

PM\_PME Messages are Posted Transaction Layer Packets (TLPs) that inform the PM software which agent within the PCI Express hierarchy has requested a PM-state change. PM\_PME Messages are always routed toward the Root Complex.

PCI Express components are permitted to wake the system from any supported PM state, through the request of a PME.

When a PEX 8609 Transparent downstream Port is in the D3hot Device PM state, the following Hot Plug and/or PCI Express Hot Plug events cause the **PCI Power Management Status and Control** register *PME Status* bit (offset 44h[15]) to be Set:

- For Hot Plug-capable Transparent downstream Ports
  - *Presence Detect Changed* (logical OR of PRSNT# (I/O Expander PRSNT# input), and SerDes Receiver Detect<sup>a</sup> on Lane(s) associated with that Port)
  - *Attention Button Pressed*
  - *Power Fault Detected*
  - *MRL Sensor Changed*
  - *Command Completed*
  - *Link Bandwidth Management Status*
  - *Link Autonomous Bandwidth Status*
- For non-Hot Plug-capable Transparent downstream Ports
  - *Presence Detect Changed* (SerDes Receiver Detect<sup>a</sup> on Lane(s) associated with that Port)
  - *Data Link Layer State Changed*

This causes the downstream Port to generate a PM\_PME Message, if the **PCI Power Management Status and Control** register *PME Enable* bit (offset 44h[8]) is Set.

---

*a. The SerDes Receiver Detect mechanism is comprised of the **Even/Odd Port Receiver Detect Status** register Receiver Detected on Lane x bits (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port – Even Ports, offset 200h[27:24], and Odd Ports, offset 204h[27:24]) or Hot Plug PRSNT# (from external I<sup>2</sup>C I/O Expander) input for the Port.*

## Chapter 14 Transparent Port Registers

### 14.1 Introduction

This chapter defines the PEX 8609 Transparent Port registers. Each PEX 8609 Port has its own Configuration, Capability, Control, and Status register space. The register mapping is the same for each Port. (Refer to [Table 14-1](#).) This chapter also presents the PEX 8609 programmable registers and the order in which they appear in the register map. Register descriptions, when applicable, include details regarding their use and meaning in the upstream Port and downstream Ports. (Refer to [Table 14-4](#).) Other registers are defined in:

- [Chapter 16, “NT Port Virtual Interface Registers – NT Mode Only”](#)
- [Chapter 17, “NT Port Link Interface Registers – NT Mode Only”](#)
- [Chapter 18, “DMA Interface Registers – DMA Mode Only”](#)

**Note:** For Chip-specific registers (those that exist only in Port 0), if Port 0 is a Legacy NT Port, then those registers exist only in the NT Port Virtual Interface.

All PEX 8609 registers can be accessed by Configuration or Memory Requests.

For further details regarding register names and descriptions, refer to the following specifications:

- *PCI r3.0*
- *PCI Power Mgmt. r1.2*
- *PCI-to-PCI Bridge r1.2*
- *PCI Express Base r2.0*
- *I<sup>2</sup>C Bus v2.1*

## 14.2 Type 1 Port Register Map

Table 14-1 defines the Transparent mode Type 1 Port register mapping.

**Table 14-1. Type 1 Port Register Map**

## 14.3 Port Register Configuration and Map

The PEX 8609 Port registers are configured similarly – not all the same. Port 0 includes more Device-Specific registers than the other Ports. Port 0 also contains registers that are used to set up and control the PEX 8609, as well as a serial EEPROM interface, I<sup>2</sup>C Slave interface, and SMBus Slave interface logic and control. The Port registers contain setup and control information specific to each Port.

Table 14-2 defines the Port register configuration and map.

**Table 14-2. Port Register Configuration and Map**

| Register Types                                                                                     | Port 0                                                                                                                                                                                                                                | Ports 1, 4, 5, 6, 7, 8, and 9 |
|----------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------|

| Power Budget Extended Capability Registers (Offsets 138h – 144h)                                   | Upstream Port 138h – 144h                                                                                                                                                                                                             |                               |
| Virtual Channel Extended Capability Registers (Offsets 148h – 1BCh)                                | 148h – 1BCh                                                                                                                                                                                                                           | 148h – 1BCh                   |
| WRR Port Arbitration Table Registers (Offsets 1A8h – 1BCh)                                         | When Weighted Round Robin (WRR) is enabled, the Arbiter is parked on the upstream Port, if the upstream Port is Port 0 through Port 3; if the upstream Port is on a higher-numbered Port, the Arbiter is parked on Port 0 1A8h – 1BCh |                               |
| Device-Specific Registers (Offsets 1C0h – 51Ch)                                                    |                                                                                                                                                                                                                                       |                               |
| Device-Specific Registers – Error Checking and Debug (Offsets 1C0h – 1FCh)                         | 1C0h – 1FCh                                                                                                                                                                                                                           | 1E0h – 1ECh, 1F8h, 1FCh       |
| Device-Specific Registers – Physical Layer (Offsets 200h – 25Ch)                                   | 200h – 25Ch                                                                                                                                                                                                                           |                               |
| Device-Specific Registers – Serial EEPROM (Offsets 260h – 26Ch)                                    | 260h – 26Ch                                                                                                                                                                                                                           |                               |
| Device-Specific Registers – Miscellaneous Control (Offset 28Ch)                                    | 28Ch                                                                                                                                                                                                                                  |                               |
| Device-Specific Registers – I <sup>2</sup> C Slave Interface (Offsets 290h – 2C4h)                 | 290h – 2C4h                                                                                                                                                                                                                           |                               |
| Device-Specific Registers – Bus Number CAM (Offsets 2C8h – 304h)                                   | 2C8h – 304h                                                                                                                                                                                                                           |                               |
| Device-Specific Registers – I/O CAM (Offsets 308h – 340h)                                          | 308h – 340h                                                                                                                                                                                                                           |                               |
| Device-Specific Registers – SMBus Slave Interface (Offset 344h)                                    | 344h                                                                                                                                                                                                                                  |                               |
| Device-Specific Registers – Address-Mapping CAM (Offsets 348h – 444h)                              | 348h – 444h                                                                                                                                                                                                                           |                               |
| Device-Specific Registers – Vendor-Specific Dual Cast Extended Capability (Offsets 448h – 51Ch)    | 448h – 51Ch                                                                                                                                                                                                                           |                               |
| ACS Extended Capability Registers (Offsets 520h – 52Ch)                                            | 520h – 52Ch                                                                                                                                                                                                                           | 520h – 52Ch                   |
| Device-Specific Registers (Offsets 530h – F8Ch)                                                    |                                                                                                                                                                                                                                       |                               |
| Device-Specific Registers – Virtual Channel Weighted Round Robin Arbitration (Offsets 530h – 540h) | Upstream Port 530h – 540h                                                                                                                                                                                                             |                               |
| Device-Specific Registers – Read Pacing (Offsets 544h – 554h)                                      | Upstream Port 544h – 554h                                                                                                                                                                                                             |                               |

**Table 14-2. Port Register Configuration and Map (Cont.)**

| Register Types                                                                                                                     | Port 0      | Ports 1, 4, 5, 6, 7, 8, and 9 |
|------------------------------------------------------------------------------------------------------------------------------------|-------------|-------------------------------|
| Device-Specific Registers – Port Configuration (Offsets 574h – 628h)                                                               | 574h – 628h |                               |
| Device-Specific Registers – General-Purpose Input/Output (Offsets 62Ch – 65Ch)                                                     | 62Ch – 65Ch |                               |
| Device-Specific Registers – Ingress Control and Port Enable (Offsets 660h – 67Ch)                                                  | 660h – 67Ch |                               |
| Device-Specific Registers – IOCAM Base and Limit Upper 16 Bits (Offsets 680h – 6BCh)                                               | 680h – 6BCh |                               |
| Device-Specific Registers – Base Address Shadow (Offsets 6C0h – 73Ch)                                                              | 6C0h – 73Ch |                               |
| Device-Specific Registers – Virtual Channel Resource Control Shadow, DMA BAR, and DMA Read and Write Latency (Offsets 740h – 83Ch) | 740h – 83Ch |                               |
| Device-Specific Registers – Ingress Credit Handler Port Pool (Offsets 940h – 94Ch)                                                 | 940h – 94Ch |                               |
| Device-Specific Registers – Vendor-Specific Extended Capability 2 (Offsets 950h – 95Ch)                                            | 950h – 95Ch | 950h – 95Ch                   |
| Device-Specific Registers – DMA Port Credit (Offsets 978h – 97Ch)                                                                  | 978h – 97Ch |                               |
| Device-Specific Registers – ACS Extended Capability (Offsets 980h – 9FCh)                                                          | 980h – 9FCh |                               |
| Device-Specific Registers – Ingress Credit Handler Threshold (Offsets A00h – B7Ch)                                                 | A00h – B7Ch |                               |
| Device-Specific Registers – Physical Layer (Offsets B80h – C30h)                                                                   | B80h – C30h |                               |
| Device-Specific Registers – Port Configuration Header (Offsets E00h – E3Ch)                                                        | E00h – E3Ch |                               |
| Device-Specific Registers – Physical Layer (Offsets E40h – EFCh)                                                                   | E40h – EFCh |                               |
| Device-Specific Registers – Source Queue Weight and Soft Error (Offsets F00h – F3Ch)                                               | F00h – F3Ch | F10h                          |

| Advanced Error Reporting Extended Capability Registers (Offsets FB4h – FDCh)                                                       | FB4h – FDCh | FB4h – FDCh                   |

Table 14-3 lists registers that are generally individual registers that support all Ports (changing the register value in one Port changes the same register in all Ports), except for the NT Port Link Interface and DMA Interface, which have their own copies (not duplicated in other Ports). Additional exceptions are also listed.

**Table 14-3. Singular Registers Shared by Multiple Ports**

| Register Offset | Register Name                                   | Comment                                                   |

## 14.4 Register Access

Each PEX 8609 Port implements a 4-KB Configuration Space. The lower 256 bytes (offsets [00h](#) through [FFh](#)) comprise the PCI-compatible Configuration Space, and the upper 960 Dwords (offsets [100h](#) through [FFFh](#)) comprise the PCI Express Extended Configuration Space. The PEX 8609 supports six mechanisms for accessing the Transparent Mode registers:

- [PCI r3.0-Compatible Configuration Mechanism](#)
- [PCI Express Enhanced Configuration Access Mechanism](#)
- [Device-Specific Memory-Mapped Configuration Mechanism](#)
- I<sup>2</sup>C Slave Interface (refer to [Section 7.2, “I<sup>2</sup>C Slave Interface”](#))
- SMBus Slave Interface (refer to [Section 7.3, “SMBus Slave Interface”](#))
- Serial Peripheral Interface (SPI) Bus (refer to [Chapter 6, “Serial EEPROM Controller”](#))

The sideband register access mechanisms (serial EEPROM, I<sup>2</sup>C, and/or SMBus) can modify Read-Only (RO) register values.

Each Port captures the Bus Number and Device Number on every Type 0 Configuration Write, as required by the *PCI r3.0*. Therefore, following a Fundamental Reset, software must initially perform a Configuration Write to each Port (using either the [PCI r3.0-Compatible Configuration Mechanism](#) or [PCI Express Enhanced Configuration Access Mechanism](#)), to allow each Port to capture its designated Bus Number and Device Number. The initial access to each Port, *for example*, could be a Configuration Write Request to a RO register, such as the **Device ID** / **Vendor ID** register (offset [00h](#)).

### 14.4.1 **PCI r3.0-Compatible Configuration Mechanism**

The *PCI r3.0*-Compatible Configuration mechanism provides standard access to the PEX 8609 Ports' first 256 bytes (the bytes at offsets 00h through FFh) of the PCI Express Configuration Space. The mechanism uses PCI Type 0 and Type 1 Configuration transactions to access the PEX 8609 Configuration registers. Each Port can convert a Type 1 Configuration Request (destined to a downstream Port or device) to a Type 0 Configuration Request (targeting the next downstream Port or device), as described below.

The PEX 8609 decodes all Type 1 Configuration accesses received on its upstream Port, when any of the following conditions exist:

- If the Bus Number in the Configuration access is not within the upstream Port's Secondary Bus Number and Subordinate Bus Number range, the PEX 8609 upstream Port responds with an Unsupported Request (UR).
- Specified Bus Number in the Configuration access is the PEX 8609 internal virtual PCI Bus Number, the PEX 8609 automatically converts the Type 1 Configuration access into the appropriate Type 0 Configuration access for the specified device.
  - If the specified device corresponds to the PCI-to-PCI bridge in one of the PEX 8609 downstream Ports, the PEX 8609 processes the Read or Write Request to the specified downstream Port register specified in the original Type 1 Configuration access.
  - If the specified Device Number does not correspond to any of the PEX 8609 downstream Port Device Numbers, the PEX 8609 responds with a UR.
- If the specified Bus Number in the Type 1 Configuration access is not the PEX 8609 internal virtual PCI Bus Number, but is the Bus Number of one of the PEX 8609 downstream Port secondary/subordinate buses, the PEX 8609 passes the Configuration access on to the PCI Express Link attached to that PEX 8609 downstream Port.
- If the specified Bus Number is the downstream Port Secondary Bus Number, and the specified Device Number is 0, the PEX 8609 converts the Type 1 Configuration access to a Type 0 Configuration access before passing it on.
  - If the specified Device Number is not 0, the downstream Port drops the Transaction Layer Packet (TLP) and generates a UR.
- If the specified Bus Number is not the downstream Port Secondary Bus Number, the PEX 8609 passes along the Type 1 Configuration access, without change.

Because the mechanism is limited to the first 256 bytes of the PCI Express Configuration Space of the PEX 8609 Ports, the [PCI Express Enhanced Configuration Access Mechanism](#) or [Device-Specific Memory-Mapped Configuration Mechanism](#) must be used to access beyond Byte FFh. The PCI Express Enhanced Configuration Access mechanism can access the registers in the PCI-compatible region, as well as those in the PCI Express Extended Configuration Space.

## 14.4.2 PCI Express Enhanced Configuration Access Mechanism

The PCI Express Enhanced Configuration Access mechanism is implemented on all PCI Express PCs and on systems that do not implement a processor-specific firmware interface to the Configuration Space. The mechanism provides a Memory-Mapped Address space in the Root Complex, through which the Root Complex translates a Memory access into one or more Configuration Requests. Device drivers normally use an application programming interface (API) provided by the Operating System (OS), to use this mechanism.

The mechanism can be used to access all PEX 8609 registers.

## 14.4.3 Device-Specific Memory-Mapped Configuration Mechanism

The Device-Specific Memory-Mapped Configuration mechanism provides a method to access the Configuration registers of all Ports in a single 128-KB Memory map, as listed in [Table 14-4](#). The registers of each Port are contained within a 4-KB range. The PEX 8609 supports a total of two, five, or eight simultaneously active Ports.

This mechanism follows the *PCI Express Base r2.0* Configuration Request Routing rules, which do not allow the propagation of Configuration Requests from downstream-to-upstream, nor peer-to-peer. By default, if any PEX 8609 downstream Port receives a Memory Request from a downstream device targeting the PEX 8609 Configuration registers, the Port:

- Responds to a Memory Read Request with a UR
- By default:
  - Silently discards a Memory Write Request (in compliance with the *PCI Express Base r2.0*)
  - or–
  - If the Port's **ECC Error Check Disable** register *Software Force Non-Posted Request* bit (offset 1C8h[3]) is Set, the Port responds with a UR

In Memory Requests that target PEX 8609 registers, the Payload Length indicated within the Memory Request Header must be 1 DWord. Lengths greater than 1 DWord result in a Completer Abort error.

To use this mechanism, program the upstream Port Type 1 Configuration Space **Base Address 0** and **Base Address 1** registers (**BAR0** and **BAR1**, offsets 10h and 14h, respectively), which are typically enumerated at boot time by BIOS and/or the OS software. After the PEX 8609 upstream Port BARs are enumerated, Port 0 registers can be accessed with Memory Reads from and Writes to the first 4 KB (0000h to 0FFFh), Port 1 registers can be accessed with Memory Reads from and Writes to the second 4 KB (1000h to 1FFFh), and so forth. (Refer to [Table 14-4](#).) Within each of these 4-KB windows, individual registers are located at the DWord offsets indicated in [Table 14-1](#).

Upstream Port **BAR0** and **BAR1** are typically enumerated at boot time, by BIOS and/or the OS software. When upstream Port **BAR0** and **BAR1** are written (by serial EEPROM, I<sup>2</sup>C Slave interface, and/or software), the PEX 8609 automatically copies the values into the Port 0 **BAR0** and **BAR1 Shadow** registers. (Refer to [Table 14-38](#) for register mapping.) The particular registers used within this block depend upon which Port is the upstream Port.

If upstream Port **BAR0** and **BAR1** are enumerated by serial EEPROM, rather than by BIOS/OS, the serial EEPROM must be programmed to also load the same values to the corresponding **BAR0** and **BAR1 Shadow** registers.

**Table 14-4. Register Offsets from Upstream Port BAR0/1 Base Address**

| Port Number | Internal Register<br>4-KB Memory Space Range | Location Range |
|-------------|----------------------------------------------|----------------|
| Port 0      | 0000h to 0FFFh                               | 0 to 4 KB      |
| Port 1      | 1000h to 1FFFh                               | 4 to 8 KB      |
| Port 4      | 4000h to 4FFFh                               | 16 to 20 KB    |
| Port 5      | 5000h to 5FFFh                               | 20 to 24 KB    |
| Port 6      | 6000h to 6FFFh                               | 24 to 28 KB    |
| Port 7      | 7000h to 7FFFh                               | 28 to 32 KB    |
| Port 8      | 8000h to 8FFFh                               | 32 to 36 KB    |
| Port 9      | 9000h to 9FFFh                               | 36 to 40 KB    |

## 14.5 Register Descriptions

The remainder of this chapter details the PEX 8609 registers, including:

- Bit/field names
- Description of register functions for the PEX 8609 upstream Port and downstream Ports
- Type (*such as* RW or HwInit; refer to [Table 14-5](#) for Type descriptions)
- Whether the power-on/reset value can be modified, by way of the PEX 8609 serial EEPROM and/or I<sup>2</sup>C/SMBus Initialization feature
- Default power-on/reset value

**Table 14-5. Register Types, Grouped by User Accessibility**

| Type   | Description                                                                                                                                                                                                                                                                                                                  |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| HwInit | <b>Hardware-Initialized</b><br>Refers to the PEX 8609 Hardware-Initialization mechanism or PEX 8609 Serial EEPROM or I <sup>2</sup> C register Initialization features. RO after initialization and can only be reset with a Fundamental Reset. HwInit register bits are not modified by a Soft Reset.                       |
| RO     | <b>Read-Only</b><br>Read-Only and cannot be altered by software. Permitted to be initialized by the PEX 8609 Hardware-Initialization mechanism or PEX 8609 serial EEPROM and/or I <sup>2</sup> C register Initialization features.                                                                                           |
| ROS    | <b>Read-Only, Sticky</b><br>Same as RO, except that bits are neither initialized nor modified by a Soft Reset.                                                                                                                                                                                                               |
| RsvdP  | <b>Reserved and Preserved</b><br><b>Reserved</b> for future RW implementations. Registers are RO and must return 0 when read. Software must preserve value read for Writes to bits.                                                                                                                                          |
| RsvdZ  | <b>Reserved and Zero</b><br><b>Reserved</b> for future RW1C implementations. Registers are RO and must return 0 when read. Software must use 0 for Writes to bits.                                                                                                                                                           |
| RW     | <b>Read-Write</b><br>Read/Write and permitted to be Set or Cleared by software to the needed state.                                                                                                                                                                                                                          |
| RW1C   | <b>Write 1 to Clear Status (Transparent mode)</b><br>Indicates status when read. A status bit Set by the system (to indicate status) is Cleared by writing 1 to that bit. Writing 0 has no effect.<br><b>Read-Write, Clear Interrupt (NT mode, Doorbell interrupts)</b><br>Indicates that a value of 1 Clears the interrupt. |
| RW1CS  | <b>Write 1 to Clear, Sticky</b><br>Same as RW1C, except that bits are neither initialized nor modified by a Soft Reset.                                                                                                                                                                                                      |
| RW1S   | <b>Read-Write, Set Interrupt (NT mode, Doorbell interrupts)</b><br>Indicates that a value of 1 Sets the interrupt.                                                                                                                                                                                                           |
| RWS    | <b>Read-Write, Sticky</b><br>Same as RW, except that bits are Set or Cleared by software to the needed state. Bits are neither initialized nor modified by a Soft Reset.                                                                                                                                                     |
| RZ     | <b>Software Read Zero</b><br>Software Read always returns 0; however, software is allowed to write this register.                                                                                                                                                                                                            |

This section details the PCI-Compatible Type 1 Configuration Header registers. [Table 14-6](#) defines the register map.

| <p><b>Note:</b> If ISA Addressing mode is enabled (<b>PCI Command</b> register <b>I/O Access Enable</b> bit, offset <b>04h[0]</b>, is Set), the PEX 8609 Port forwards I/O transactions from its primary interface to its secondary interface (downstream) if an I/O address is within the range defined by the <b>I/O Base</b> and <b>I/O Limit</b> registers when the Base is less than or equal to the Limit.</p> <p>Conversely, the PEX 8609 Port forwards I/O transactions from its secondary interface to its primary interface (upstream) if an I/O address is outside this Address range. If the PEX 8609 Port does not implement an I/O Address range, the Port forwards all I/O transactions on its secondary interface upstream, to its primary interface.</p> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |      |                                    |         |

- a. Because the PEX 8609 does not consume auxiliary power, this bit is not sticky, and is always Cleared at power-on reset.
- b. With no serial EEPROM nor previous I<sup>2</sup>C programming, Reads return 00h for the **Data** and **Data Scale** registers (for all Data Selects).

This section details the Message Signaled Interrupt (MSI) Capability registers. [Table 14-8](#) defines the register map.

| <p>The interrupt sources in a PEX 8609 Port are grouped into four categories – Power Management/Hot Plug or Link State events, Device-Specific errors, GPIO-generated interrupts, and NT-Virtual Doorbell-generated interrupts.</p> <p>The quantity of allocated MSI Vectors is determined by the <b>MSI Control</b> register <i>Multiple Message Capable</i> and <i>Multiple Message Enable</i> fields (offset 48h[19:17 and 22:20], respectively). When the quantity of MSI Vectors that can be requested is:</p> <ul style="list-style-type: none"><li>• <b>Four</b> – Each interrupt category generates its own MSI Vector</li><li>• <b>Two</b> – Device-Specific errors generate their own MSI Vector, while all other categories are combined and generate the same Vector</li><li>• <b>One</b> – All interrupt categories generate the same MSI Vector</li></ul> <p>NT-Virtual Doorbell interrupts are generated only on the NT Port. The Type is the same, regardless of whether it is for a Transparent or NT Port.</p> <p><b>Notes:</b> The offset for this register changes from 58h, to 54h, when the <b>MSI Control</b> register <i>MSI 64-Bit Address Capable</i> bit (offset 48h[23]) is Cleared.</p> <p>The bits in this register can be used to mask their respective <b>MSI Status</b> register bits (offset 5Ch).</p> |                                                                                                                                                                                                                        |                        |                                    |         |           |

## 14.9 PCI Express Capability Registers (Offsets 68h – A0h)

This section details the PCI Express Capability registers. Hot Plug Capability, Command, Status, and Events are included in these registers. [Table 14-9](#) defines the register map.

### Table 14-9. PCI Express Capability Register Map

|                                                            |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |                                       |  |  |  |  |  |  |  |                     |  |  |  |  |  |  |  |           |

|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------|-------|------------------------------------|---------|
| <b>Notes:</b> For bits [6, 4:0], the default values are shown to be 1 for downstream Ports, which is true only if the Port is Parallel and/or Serial Hot Plug-capable; otherwise, the default value is 0. This also applies to bit 17 for Serial Hot Plug Ports. Serial Hot Plug-capable means that the PEX 8609 has detected that an external I <sup>2</sup> C I/O Expander is present. |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |            |       |                                    |         |

## 14.12 Power Budget Extended Capability Registers (Offsets 138h – 144h)

This section details the Power Budget Extended Capability registers. These registers work differently than the others, especially with respect to serial EEPROM Reads and Writes. *For example*, when writing to Index 5 of the upstream Port/NT Port Link Interface **Power Budget Data** register (offset 140h), write 5 into the upstream Port/NT Port Link Interface **Data Select** register *Data Select* field (offset 13Ch[7:0]), then write the value into the upstream Port/NT Port Link Interface **Power Budget Data** register. Table 14-13 defines the register map.

**Table 14-13. Power Budget Extended Capability Register Map (Upstream Port, and also the NT Port Link Interface)**

|                                                                                                                          |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |                         |  |  |  |                                            |  |  |  |  |  |  |  |  |  |  |  |      |

### 14.13 Virtual Channel Extended Capability Registers (Offsets 148h – 1BCh)

This section details the Virtual Channel Extended Capability registers, which are duplicated for each Port. [Table 14-14](#) defines the register map for one Port.

**Table 14-14. Virtual Channel Extended Capability Register Map (All Ports)**

|                                                            |  |  |  |  |  |  |  |  |  |  |  |                            |  |  |  |                                            |  |  |  |  |  |  |  |  |  |  |  |        |  |  |  |      |

### 14.13.1 WRR Port Arbitration Table Registers (Offsets 1A8h – 1BCh)

This section details the WRR Port Arbitration Table registers. Port Arbitration Table phases are used to determine Port weighting during “Weighted Round-Robin with 32 Phases” Port arbitration.

Table 14-15 defines the register map. The numbers along the top of the table indicate the 4-bit fields of each 32-bit register. There are 32 phases, and any active Port Number can go into each Port *x*, Phase *x* box.

**Note:** *The Port Arbitration Table is used only when Weighted Round-Robin (WRR) with 32-phase Port Arbitration is selected. The Arbiter is parked on the upstream Port, if the upstream Port is Port 0 through Port 3. Moreover, the fields within this register are valid only on the upstream Port. If the upstream Port is on a higher-numbered Port, the Arbiter is parked on Port 0. Furthermore, the fields within this register are valid only on Port 0 and reserved on all other Ports.*

## 14.14 Device-Specific Registers (Offsets 1C0h – 51Ch)

This section details the Device-Specific registers located at offsets 1C0h through 51Ch. Device-Specific registers are unique to the PEX 8609 and not referenced in the *PCI Express Base r2.0*. [Table 14-16](#) defines the register map.

Other Device-Specific registers are detailed in [Section 14.16](#), “Device-Specific Registers (Offsets 530h – F8Ch).”

**Note:** *It is recommended that these registers not be changed from their default values.*

### 14.14.1 Device-Specific Registers – Error Checking and Debug (Offsets 1C0h – 1FCh)

This section details the Device-Specific Error Checking and Debug registers. [Table 14-17](#) defines the register map.

**Table 14-17. Device-Specific Error Checking and Debug Register Map**

| 31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16   | 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0 |      |
|---------------------------------------------------|---------------------------------------|------|

#### 14.14.2 Device-Specific Registers – Physical Layer (Offsets 200h – 25Ch)

This section details the Device-Specific Physical Layer (PHY) registers located at offsets 200h through 25Ch. [Table 14-18](#) defines the register map.

Other Device-Specific PHY registers are detailed in:

- Section 14.16.14, “Device-Specific Registers – Physical Layer (Offsets B80h – C30h)”
- Section 14.16.16, “Device-Specific Registers – Physical Layer (Offsets E40h – EFCh)”

**Table 14-18. Device-Specific PHY Register Map  
(Offsets 200h – 25Ch) (Port 0, and also the NT Port Virtual  
Interface if Port 0 is a Legacy NT Port)**

| <p>This register is used for specifying the pre-determined quantity of Lanes that detected a Receiver during a LTSSM <i>Detect</i> state, but never detected an exit from Electrical Idle. Because the PEX 8609 has multiple Port configurations, a Mask register is used, rather than specifying a number. multiple bits are Set, and they correspond to Lanes that belong to the same Port, any of those specified Lanes can cause entry into the LTSSM <i>Polling.Compliance</i> state.</p> <p><b>Note:</b> Masking Electrical Idle detect does not affect the inferred Electrical Idle detection. Use the SerDes x Mask Electrical Idle Detect bits with caution.</p> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |       |                                    |         |

| <p>This register is used for specifying the pre-determined quantity of Lanes that detected a Receiver during a LTSSM <i>Detect</i> state, but never detected an exit from Electrical Idle. Because the PEX 8609 has multiple Port configurations, a Mask register is used, rather than specifying a number. multiple bits are Set, and they correspond to Lanes that belong to the same Port, any of those specified Lanes can cause entry into the LTSSM <i>Polling.Compliance</i> state.</p> <p><b>Note:</b> Masking Electrical Idle detect does not affect the inferred Electrical Idle detection. Use the SerDes x Mask Electrical Idle Detect bits with caution.</p> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |       |                                    |         |

| UTP Bytes 0 through 3. Used for Digital Far-End Loopback testing.<br><b>Note:</b> A 16-byte test pattern can be written to register offsets 210h through 21Ch. When User Test Pattern (UTP) transmission is enabled, Byte 0 of register offset 210h is transmitted first and Byte 3 (Byte 15 of the UTP) of register offset 21Ch is transmitted last. (Refer to <a href="#">Section 20.2.3, “Digital Loopback Master Mode,”</a> for further details.) Every byte of the UTP can be a Control or Data character. Illegal Control characters can be specified. |                                                        |      |                                    |         |

| <p>This register is used to disable or enable the LTSSM within individual Even Ports. The bits are intended to be used in lieu of placing the Port into the <i>Loopback.Active</i> state as a Loopback Master. These bits enable the test patterns to be transmitted, with or without a device attached at the far end. The recommended usage is as follows:</p> <ol style="list-style-type: none"> <li>Set the Port's <i>Disable Port x</i> and <i>Port x Quiet</i> bits. <ul style="list-style-type: none"> <li>Setting the Port's <i>Disable Port x</i> bit forces the Port into the <i>Detect.Quiet</i> state. If no device is attached, it is not necessary to Set the Port's <i>Disable Port x</i> bit.</li> <li>If 5.0 GT/s is needed, also Set the Port's <i>Test Pattern x Rate</i> bit.</li> </ul> </li> <li>If Set, Clear the Port's <i>Disable Port x</i> bit.</li> <li>Load the UTP registers and enable UTP transmission, or just enable PRBS transmission.</li> </ol> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |       |                                    |         |
| 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | <p><b>Disable Port 0</b></p> <p>While Port 0 is disabled, Receiver termination is disabled and the SerDes that belong to the Port are placed into the L1 Link PM state.</p> <p>0 = Enables Link Training operation on Port 0.</p> <p>1 = LTSSM remains in the <i>Detect.Quiet</i> state on Port 0, if it is currently in, or returns to, that state. Unconditionally disables Port 0. This is different from the Link Training and Status State Machine (LTSSM) <i>Disabled</i> state, in that Port 0 does not attempt to enter this state. If Port 0 is idle, it ceases attempting to detect a Receiver. If Port 0 is up, it immediately returns to the <i>Detect.Quiet</i> state and remains there. No Electrical Idle Ordered-Set (EIOS) is sent, which could force any connected device to the <i>Recovery</i> state, and then to the LTSSM <i>Detect</i> state. Port 0 remains disabled until this bit is Cleared.</p> | RWS   | Yes                                | 0       |

Once in the <i>Detect.Quiet</i> state, Receiver termination is enabled and the Transmitters are placed into the L0 Link PM state. Port 8 can now transmit test patterns (PRBS or UTP), with or without an attached device and without being in the <i>Loopback.Active</i> state.</p> <p>0 = LTSSM is allowed to exit the <i>Detect.Quiet</i> state in a normal manner (no effect on the LTSSM)</p> <p>1 = LTSSM remains in the <i>Detect.Quiet</i> state on Port 8 if it is currently in, or returns to, that state</p> <p><b>Note:</b> Use this bit when it is necessary to transmit some data pattern, without first entering the <i>Loopback.Active</i> state as a <i>Loopback Master</i>.</p> | RWS   | Yes                                | 0       |

| <p>This register is used to disable or enable the LTSSM within individual Odd Ports. The bits are intended to be used in lieu of placing the Port into the <i>Loopback.Active</i> state as a Loopback Master. These bits enable the test patterns to be transmitted, with or without a device attached at the far end. The recommended usage is as follows:</p> <ol style="list-style-type: none"> <li>Set the Port's <i>Disable Port x</i> and <i>Port x Quiet</i> bits. <ul style="list-style-type: none"> <li>Setting the Port's <i>Disable Port x</i> bit forces the Port into the <i>Detect.Quiet</i> state. If no device is attached, it is not necessary to Set the Port's <i>Disable Port x</i> bit.</li> <li>If 5.0 GT/s is needed, also Set the Port's <i>Test Pattern x Rate</i> bit.</li> </ul> </li> <li>If Set, Clear the Port's <i>Disable Port x</i> bit.</li> <li>Load the UTP registers and enable UTP transmission, or just enable PRBS transmission.</li> </ol> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |       |                                    |         |

| 21     | <p><b>Analog Loopback Enable</b></p> <p>0 = PEX 8609 enters Digital Loopback Slave mode if an external device sends at least two consecutive TS1 Ordered-Sets that have the <i>Loopback</i> bit exclusively Set in the TS1 Training Control symbol. The PEX 8609 then loops back data through the Elastic buffer, 8b/10b decoder, and 8b/10b encoder.</p> <p>1 = Loopback point of all Ports is before the Elastic buffer. This means that data recovered from the Serial data in the recovered Receive Clock domain is re-serialized, then re-transmitted in that same recovered clock domain. This allows the Loopback Master to transmit and receive a user test pattern (UTP) in an asynchronous clocking system. It is also the <b>required</b> mode for re-transmitting a PRBS pattern back to the Loopback Master. Overrides the Lane's Parallel "Digital" Loopback Setting (<b>Even/Odd Port Physical Test</b> register <i>Lane x Parallel Loopback Path Enable</i> bits – Even Ports, offset <a href="#">228h</a>[28:26, 24], and Odd Ports, offset <a href="#">22Ch</a>[28:26, 24]).</p> <p><b>Note:</b> This bit must be Cleared when using Parallel "Digital" Loopback.</p> | RWS   | Yes                                | 0       |
| 22     | <b>Reserved</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | RsvdP | No                                 | 0       |

| <p>There are two <b>Even/Odd Port SerDes Quad x Diagnostic Data</b> (Diagnostic Data) registers, one for each SerDes quad, at offsets <a href="#">240h</a> and <a href="#">244h</a>, in Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port. The contents of the Diagnostic Data registers reflect the performance of the SerDes that are selected by the registers' <i>SerDes Diagnostic Data Select</i> bits (field [25:24]).</p> <p>When field [25:24] is Cleared, the information in that Diagnostic Data register is for the first SerDes within that SerDes quad. When field [25:24] is programmed to 01b, the information in that Diagnostic Data register is for the second SerDes within that SerDes quad. Following this pattern, a value of 10b indicates the third SerDes within that SerDes quad, and a value of 11b indicates the fourth SerDes within that SerDes quad.</p> <p>This register is used to retrieve Diagnostic Test results for SerDes[0-3].</p> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |      |                                    |         |

| <p>There are two <b>Even/Odd Port SerDes Quad x Diagnostic Data</b> (Diagnostic Data) registers, one for each SerDes quad, at offsets <b>240h</b> and <b>244h</b>, in Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port. The contents of the Diagnostic Data registers reflect the performance of the SerDes that are selected by the registers' <i>SerDes Diagnostic Data Select</i> bits (field [25:24]).</p> <p>When field [25:24] is Cleared, the information in that Diagnostic Data register is for the first SerDes within that SerDes quad. When field [25:24] is programmed to 01b, the information in that Diagnostic Data register is for the second SerDes within that SerDes quad. Following this pattern, a value of 10b indicates the third SerDes within that SerDes quad, and a value of 11b indicates the fourth SerDes within that SerDes quad.</p> <p>This register is used to retrieve Diagnostic Test results for SerDes[4-7].</p> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |      |                                    |         |

| <p>This register contains PHY Safety bits that are associated with the Even Ports. It also contains Controls and Status for Link width re-configuration on Ports that are x4 capable in the Even PHY partition.</p> <p>Link width fields in this register are provided, to enable software to direct Link width Up/Down configuration. The Link width fields are loaded with the Target Link width, which should not exceed the originally negotiated Link width, and afterward, the <a href="#">Link Control</a> register <a href="#">Retrain Link</a> bit (offset 78h[5]) is Set. If the Target Link width is not equal to the current Link width, the LTSSM transitions from <i>Recovery</i> to <i>Configuration</i>, then re-negotiates the Link width.</p> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |       |                                    |         |
| 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | <p><b>Port 0 Downtrain Disable</b></p> <p>This bit supports Port 0, at up to x4 Link widths.</p> <p>1 = Port 0 does not reduce its Link width during Link configuration, to eliminate faulty Lanes. Instead, the LTSSM returns to its <i>Detect</i> state and Retries Link training. This continues until the Link is able to train on all Lanes that detected a Receiver.</p> <p><b>Caution:</b> <i>This bit should be used with extreme caution, because its use could lead to an endless loop, in which the Link never reaches the L0 Link PM state.</i></p> | RWS   | Yes                                | 0       |

| <p>This register contains PHY Safety bits that are associated with the Odd Ports. It also contains Controls and Status for Link width re-configuration on Ports that are x4 capable in the Odd PHY partition.</p> <p>Link width fields in this register are provided, to enable software to direct Link width Up/Down configuration. The Link width fields are loaded with the Target Link width, which should not exceed the originally negotiated Link width, and afterward, the <a href="#">Link Control</a> register <a href="#">Retrain Link</a> bit (offset 78h[5]) is Set. If the Target Link width is not equal to the current Link width, the LTSSM transitions from <i>Recovery</i> to <i>Configuration</i>, then re-negotiates the Link width.</p> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |       |                                    |         |
| 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | <p><b>Port 1 Downtrain Disable</b></p> <p>This bit supports Port 1, at up to x4 Link widths.</p> <p>1 = Port 1 does not reduce its Link width during Link configuration, to eliminate faulty Lanes. Instead, the LTSSM returns to its <i>Detect</i> state and Retries Link training. This continues until the Link is able to train on all Lanes that detected a Receiver.</p> <p><b>Caution:</b> This bit should be used with extreme caution, because its use could lead to an endless loop, in which the Link never reaches the L0 Link PM state.</p>            | RWS   | Yes                                | 0       |

### 14.14.5 Device-Specific Registers – I<sup>2</sup>C Slave Interface (Offsets 290h – 2C4h)

This section details the Device-Specific I<sup>2</sup>C Slave Interface register. [Table 14-22](#) defines the register map.

The I<sup>2</sup>C Slave Interface is described, in detail, in [Section 7.2, “I<sup>2</sup>C Slave Interface.”](#)

**Table 14-22. Device-Specific I<sup>2</sup>C Slave Interface Register Map (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port)**

## 14.14.6 Device-Specific Registers – Bus Number CAM (Offsets 2C8h – 304h)

This section details the Device-Specific Bus Number Content-Addressable Memory (BusNoCAM) registers, which are used to determine the Configuration TLP Completion routing. These registers contain mirror copies of the **Primary Bus Number**, **Secondary Bus Number**, and **Subordinate Bus Number** registers (offset 18h[23:16, 15:8, and 7:0], respectively), for each PEX 8609 Port. Table 14-23 defines the register map.

The BusNoCAM registers are automatically updated by hardware. **Modifying these registers by writing to the addresses listed here is not recommended.**

**Table 14-23. Device-Specific BusNoCAM Register Map (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port)**

### 14.14.7 Device-Specific Registers – I/O CAM (Offsets 308h – 340h)

This section details the Device-Specific I/O Content-Addressable Memory (IOCAM) registers, which are used to determine I/O Request routing. These registers contain mirror copies of the **I/O Base** and **I/O Limit** registers (offset 1Ch[7:0 and 15:8], respectively), for each PEX 8609 Port. Table 14-24 defines the register map.

The IOCAM registers are automatically updated by hardware. **Modifying these registers by writing to the addresses listed here is not recommended.**

**Table 14-24. Device-Specific IOCAM Register Map (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port)**

#### 14.14.8 Device-Specific Registers – SMBus Slave Interface (Offset 344h)

This section details the Device-Specific SMBus Slave Interface register. [Table 14-22](#) defines the register map.

The SMBus Slave Interface is described, in detail, in [Section 7.3, “SMBus Slave Interface.”](#)

**Table 14-25. Device-Specific SMBus Slave Interface Register Map  
(Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port)**

#### 14.14.9 Device-Specific Registers – Address-Mapping CAM (Offsets 348h – 444h)

This section details the Device-Specific Address-Mapping Content-Addressable Memory (AMCAM) registers, which are used to determine Memory Request routing. These registers contain mirror copies of the **Memory Base and Limit**, **Prefetchable Memory Base and Limit**, **Prefetchable Memory Upper Base Address**, and **Prefetchable Memory Upper Limit Address** registers (offsets 20h, 24h, 28h, and 2Ch, respectively), for each PEX 8609 Port. Table 14-26 defines the register map.

The AMCAM registers are automatically updated by hardware. **Modifying these registers by writing to the addresses listed here is not recommended.**

**Table 14-26. Device-Specific AMCAM Register Map**  
(Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port)

#### 14.14.10 Device-Specific Registers – Vendor-Specific Dual Cast Extended Capability (Offsets 448h – 51Ch)

This section details the Device-Specific, Vendor-Specific Dual Cast Extended Capability registers. [Table 14-27](#) defines the register map.

**Table 14-27. Device-Specific, Vendor-Specific Dual Cast Extended Capability Register Map (Port 0, and also the NT Port Virtual Interface if Port 0 is a Legacy NT Port)**
